Abstract

Since 1988, the Greenland Institute of Natural Resources has annually conducted a bottom trawl survey off West Greenland. The survey was initially designed with the focus to evaluate the biomass and abundance of the Northern shrimp (*Pandalus borealis)*, but fish catches have systematically been recorded since 1992. The gear was changed prior to the 2005 survey from a shrimp trawl with steel bobbins to a slightly larger shrimp trawl with rock-hoppers. In 2008, the survey was expanded to include The East Greenland shelf area using the same gear and depth range. This paper contain biomass and abundance indices, length distributions and maps of survey densities for Greenland halibut (Reinhardtius hippoglossoides), Atlantic cod (*Gadus morhua*), redfish (Sebastes norvegicus and Sebastes Mentella), Atlantic wolffish (Anarhichas lupus), Spotted wolffish (Anarhichas minor), American plaice (Hippoglossoides platessoides) and Thorny skate (Amblyraja radiate). The appendix contains total biomass and abundance estimates for Elasmobranchs, Teleosts, Cephalopods and crustaceans excl. Shrimp. In West Greenland, the Greenland halibut abundance and biomass has been in a decreasing trend for a decade and the 2016 index is among the lover observed and remain below the most recent decade average. The 2016 survey indicated a major decline in the offshore cod stock in West Greenland (NAFO 1A-1E) with 80% in abundance and 86% in biomass compared to 2015. The biomass of golden redfish and deep-sea redfish in West Greenland have increased in the past few years, but the abundance of redfish, mainly juvenile, has decreased about a factor 20 since the beginning of the time series, indicating continued failing recruitment in the area. Both the East

Greenland and West Greenland shelf (1AB) are known nursery grounds for redfish. Abundance and biomass indices of spotted wolffish, Atlantic wolffish, American plaice and thorny skate have been in an increasing trend throughout the time series in West Greenland.

Materials and Methods

The Greenland Shrimp and Fish survey in West Greenland (SFW survey)

The survey has throughout the time series been conducted with the 722 GRT stern trawler M/Tr 'Pâmiut'. The survey design, the area coverage and the trawl and its rigging has been unchanged since 2005. The survey period is June –July in West Greenland and August in East Greenland.

The Survey Gear and trawl: The survey initially used a Skjervoy 3000/20 trawl with steel bobbin gear and double bag. In 2005, the skjervoy trawl was replaced by a Cosmos trawl (Wieland and Bergström, 2005). Until 2003, *Greenland Perfect* trawldoors were used (9.25 m^2, 2.4 tons), but they were replaced in 2004 by Injector International trawl doors (7.5 m^2, 2.8 tons) to facilitate the trawl change in 2005. Calibration experiments were conducted in the main shrimp areas in 2004 and 2005 and a formal analysis of conversion factors were established for shrimp (Rosing and Wieland, 2005). Preliminary conversion factors for a few commercial fish species were derived as described by Rosing and Wieland (2005) and are given in table 3. However, the calibration factors were never finally evaluated and in some cases (particularly cod) the calibration factors relied on few data. Indeed, without calibration the two separate time series seems well connected for most species.

Survey area and stratification: The trawl survey initially covered the traditional offshore shrimp area, between 60º - 72º north, depth 150-600m. In 1991, the area was extended to include Disko Bay. The area is delimited by a line 3nm off the base line and the 600 m depth curve. Areas shallower than 150 m was initially rather unsystematically covered, but from 2004 two extra depth zones have been formally included (50-100m, and 100-150m).
The stratification is based on designated 'Shrimp Areas' that is divided into depth zones of: 151-200, 201-300, 301-400 and 401-600 m, as based on depth contour lines (figure. 1). The depth zones 0-100 m and 100-150m are delimited by the NAFO Subdivision boundaries. The ""shrimp Areas" and their sizes are provided in table 1. The number of valid hauls by year and strata are is listed in table 2. Fish species was prior to 2007 analysed using a re-stratification that followed the NAFO divisions. Re-stratification implies a potential bias and the survey information from 2005 and onwards has therefore been reanalysed in accordance with the shrimp strata actually used in the survey. If strata had no stations in a given year, the neighbouring strata with stations in that year is geographically enhanced to include of the non-visited strata. This way the total area surveyed is maintained (since 2005). Tow duration was over the years gradually reduced from 60 min. (prior to 1997) to 30 and has been fixed to 15 min since 2005 (Wieland and Storr-Paulsen 2006). Towing speed has been about 2.5 knots throughout the years. Survey abundance and biomass is expressed per swept area: Wingspread*towed distance, where wingspread is inferred from Scanmar recordings and the towed distance is measured by GPS.

Allocation of stations per strata. Trawl stations are allocated to strata with the objective to minimise the variances of the shrimp biomass. The allocation algorithm utilises the historically observed shrimp variances where highest weight is placed on the most recent information. Stations were initially selected at random, but since 1999 station positions were chosen to secure a minimum distance between stations. Since 1998 about half the haul positions were randomly selected from the previous year hauls and the rest of the hauls being selected at random.

The Greenland Shrimp and Fish survey in East Greenland (SFE survey)

The survey is carried out with the same gear and survey protocols as used in West Greenland after 2005. Stratification is based on the "Q-areas" used for the East Greenland survey for Greenland

halibut. The areas are further depth stratified into 0-200 m, 200-400m and 400-600 m zones, the areas are shown in figure 1 and the area sizes are given in table 1. In East Greenland, bottom conditions severely restrict the areas that can be trawled and in some strata, stations are randomly selected from historical known trawl-able sites.

Results

Greenland halibut (*Reinhardtius hippoglossoides*).

Greenland halibut can be found in all divisions, but the highest concentrations are found in the important nursery areas in division 1A, 1B-north and Disko Bay (table 4 and5). The abundance indices is mainly driven by year to year variability in the number of one- and two-year old recruits, which by number typically constitute 80-90% in numbers of the Greenland halibut taken in the survey.
The biomass and abundance indices increased gradually until the gear change in 2005 (figure 2). After the gear change the general trend in the abundance indices has been decreasing, with the exception of record high numbers of one-year old recruits observed in 2011 and 2013 (figure 2). Although the biomass index is slightly higher in 2016 the decreasing trend remains. In West Greenland clear modes can be found in the length distribution at 12-15 and 23 cm every year corresponding to year-classes 1 and 2 (figure 14). Distribution of survey catches in number pr. km^2 and kg pr. km^2 are given in figure 21. In East-Greenland, recruits are rarely seen and both abundance and biomass indices are much lower on the shallow parts of the East Greenlandic shelf areas.

Greenland halibut recruitment.

A recruitment index was estimated for the entire survey area. By means of the Petersen-method ages 1, 2 and 3+ were separated in the survey catches. To allow comparison of abundance throughout the time series, the 2005 to 2016 catches were converted by a conversion factors to adjust the new Cosmos trawl catches to the old Skjervoy trawl catches. For Greenland halibut the conversion were length dependent and x in the equations is the individual fish length (Table 3).
The number of one-year-old fish in the total survey area including Disko Bay increased gradually from 1996 to a peak of 500 million in 2001 (Fig. 9). During the 00' the recruitment was stable at around 300 mill. The number of one-year old peaked again in 2011 with 530 million, which is the highest estimate in the time series. The recruitment decreased in 2012 where the 2011 year-class was estimated to 175 mill., the lowest estimate since 1996 and at the level of the early 90's. The recruitment has fluctuated since the with several good year classes. The estimate of the 2015 year class was estimated as 241 mill which is slightly below the average for the time series (270 mill.). Almost all the one year old fish were found in Div. 1AS and Div. BN (Fig. 10).
The offshore recruitment has been rather stable between 2003 and 2010. The recruitment increased to the highest level in the time series in 2011 to decrease to lowest level seen since 1997 (1996 year-class) in 2012. The offshore recruitment has fluctuated since the with good 2012 and 2014 year-classes. The recruitment decreased again in 2016 and the 2015 year-classes was estimated to 178 mill which is about an average level (Fig. 11). The decrease in recruitment between 2015 and 2016 was seen in all divisions. 74.6% of the one year old fish was found in the off shore areas (Fig.12).

Greenland halibut in Disko Bay is believed to be recruited from a spawning area in the central part of the Davis Strait. The recruitment to Disko Bay has been decreasing between 2003 and 2008 but increased since then to the highest level seen since 2001 in 2011. Since then the recruitment has been gradually decreasing and was the second lowest in the time series in 2015 (Fig. 11) where only 11.4% of the recruitment ended up in Disco Bay. In 2016, the recruitment in Disko Bay increased

again but is still at a low level despite that 25.6% of the recruits were found in Disk Bay which is close to normal (Fig. 12). Generally there is a steep decline between abundance at age 1 and age 2 and 3+ which also was observed in the 2016 survey (Fig. 13).

Cod (*Gadus morhua*)

The Atlantic cod (Gadus morhua) stock complex in Greenland is considered to be composed of primarily three different stock components; inshore cod, West Greenland Cod and East Greenland/Iceland offshore cod. **Inshore cod** are believed to be relatively stationary, as tagging experiments showed that most (82-86 %) of the cod recaptured were found in the same area as tagged (Hovgård and Christensen 1990). **West Greenland offshore** cod that historically has been spawning along the banks of the West Greenland's coast (Wieland and Hovgaard 2002, Therkildsen et al. 2013). **East Greenland/Icelandic offshore cod** presently spawning on several banks of the East Greenland's coast. Occasionally larvae drift from East Greenlandic and Icelandic spawning grounds with the Irminger current and settle in South and West Greenland waters, thereby contributing to the offshore as well as to local fjord populations in Greenland. Based on genetics and tagging results it was decided to split the advice for the offshore stock in two units in 2015: West Greenland offshore stock in the area NAFO 1A-1E and East Greenland offshore stock in the area NAFO 1F and ICES 14b.
The 2016 survey indicated a major decline in the offshore cod stock in West Greenland (NAFO 1A-1E) with 80% in abundance and 86% in biomass compared to 2015. In East Greenland the survey indicated (NAFO 1F and ICES XIV) a further decrease since 2013 in terms of biomass (31% compared to 2015) returning to the 2008-2012 level. For further information on cod see the ICES Report of the North-Western Working Group (Anon., 2016)

Demersal Redfish (*Sebastes sp.*) combined.

Two species of redfish are common in the area, golden redfish, *Sebastes norvegicus* and deep-sea redfish *Sebastes mentella*. Due to difficulties in identification of species in some years redfish were classified as *Sebastes sp.* (prior to 2007). After 2007 redfish smaller than approximately 18-20 cm has been classified as juvenile redfish *Sebastes sp.* and larger redfish are classified on a species level. The distinction between golden redfish and deep-sea redfish is however not easy. Golden redfish and deep-sea redfish combined biomass decreased during the 1990's (mainly juvenile) but has increased in West Greenland in the most recent decade (mainly larger individuals) (fig 4a). In comparison, the abundance of redfish has been almost continuously decreasing in West Greenland since the 1991 (fig 4a). Densities by haul in number pr. km^2 and kg pr. km^2 are given in figure 23 – 26.

Redfish recruitment.

The high numbers of redfish in the survey in the 1990's were mainly recruits concentrated in division 1AS and 1B. The combined abundance index for both redfish species can be viewed as a continuous decrease in the number of recruits since the 1990's (fig 4a). The decreasing numbers of recruits has continued in both East Greenland and West Greenland since 2008 with a almost complete lack of recruits in the most recent 4 years (fig 4b and 16). Annual growth increments of 4 cm are indicated by repeatedly pronounced peaks in length compositions at 7-8 cm and around 12 cm probably corresponding to age 1 and 2 (Nedreaas, 1990).

Classification of redfish by species.

A separation of redfish by species has been attempted since 2007 (table 10-15, figure 4b-d and 16).

Deep-sea redfish *S. mentella*

In East Greenland, deep-sea redfish abundance has decreased substantially since 2008, but a gradual shift in the length distribution from around 18-30 to 30-45 cm has maintained the biomass at a higher level (fig 4c). In West Greenland, the abundance and biomass of deep-sea redfish has increased almost continuously since 2008 (fig 4c) with a single large haul providing almost 70% of the total biomass estimate. The sudden increase in larger individuals of deep-sea redfish in a situation with decreasing West Greenland recruitment, could indicate a connection with the Icelandic, East Greenlandic stock. Indeed, tow densities by haul reveal an almost continuous distribution of deep-sea redfish around cape farewell (fig 24).

Golden Redfish *S. Norvegicus*

In East Greenland, the biomass index for Golden redfish increased from the 2008-2010 period and remained higher since then (fig 4d). In 2016, the length distribution ranged from 25 to 40 cm in East Greenland with a clear mode around 30 cm (not shown). In West Greenland, golden redfish biomass has increased in recent years (table 15 and fig 4d). The increasing biomass since 2013 occurs in division 1E and 1F and is caused by one or 2 hauls containing larger individuals (figure 26) contributing more than half the total West Greenland biomass. In 2016, a single haul in division 1E consisted of large golden redfish between 45-70cm and provided 80% of the total biomass estimate. The sudden increase in larger individuals of redfish could indicate a connection with the Icelandic, East Greenlandic stock. For golden redfish, tow densities by haul also reveal an almost continuous distribution around cape farewell without any obvious geographical separation (fig 25). However, the increasing biomass in West Greenland during a period of decreasing recruitment could be related to an increased survival of redfish since the implementation of sorting grids in the shrimp-fishery in 2002.

For further information on redfish in East Greenland see the ICES Report of the North-Western Working Group (Anon., 2017)

American plaice (*Hippoglossoides platessoides*).

In West Greenland, American plaice is common in all divisions (table 16,17 and figure 27). The biomass and abundance indices have fluctuated substantially in recent years, but the general trend has been increasing both prior to and after the gear change (table 16, 17 and figure 5). Clear modes can be found at 5 and 15 cm indicating new incoming year-classes and individuals larger than 45 cm are rarely seen in Greenland (figure. 17). The highest concentrations are mainly found in West Greenland (figure 27). In East-Greenland, both abundance and biomass indices are much lower on the shallow parts of the East Greenlandic shelf areas.

Atlantic wolffish (*Anarhichas lupus)*

Atlantic wolffish is common in all divisions, in both East and West Greenland (figure 28). Previously Atlantic wolffish had its main distribution south of 68°N, but it has shifted further north since the beginning of the time series (table 18, 19 and figure 6). Although the abundance and biomass indices tends to have extreme values in some years, the underlying trends has been increasing since the beginning of the time series and the non-calibrated indices seems well connected. The length distribution reveals the dominance of smaller fish (figure. 18).

Spotted wolffish (*Anarhichas minor*)

Spotted wolffish are common in all divisions in both East and West Greenland, inshore and offshore. Abundance and biomass indices have increased throughout the time series and the non-calibrated indices seems well connected (Table 20, 21 and figure 7). The length distribution ranges from 10-120 cm and modes at 13 and 100 cm likely represents one-year old recruits and individuals at L_{max} (figure 19). Recruits and juvenile individuals are mainly found in North-west Greenland (1A) (figure 19 and 29).

Thorny skate *(Amblyraja radiata*)

In West Greenland, thorny skate is common in all divisions, but the majority of both the biomass and abundance is located in West Greenland (fig 8 and 30). Abundance and biomass indices have increased throughout the time series and the non-calibrated indices seems well connected (table 22, 23 and figure 8). Although Lmax for thorny skates is reported to be more than 100 cm, it has been suggested that North American thorny skate grows to larger body size than East Atlantic individuals. Since individuals larger than 55 cm are rarely seen in Greenland waters and all individuals about 50 cm are fully mature, it seems likely that thorny skates in Greenland resemble East Atlantic stocks. During the most recent years thorny skate length distributions have revealed clear modes at 10-15 cm and 35-50 cm probably corresponding to recruits and overlapping year-classes of adult individual (figure. 20).

Other species

The Appendix contains biomass and abundance estimates for elasmobranchs, teleosts, cephalopods and crustaceans excl. Shrimp for the West-Greenland part of the GINR shrimp fish survey including the West-Greenlandic Shelf part of NAFO div 0A.

Discussion

Catch-ability is set at 1 for all species. However, since swept area is calculated for the trawl excluding doors and bridles, catchability may be higher than 1 for some species and below 1 for other species, implying that both biomass and abundance should be regarded as index values only, not absolute values.

Index changes from the end of the 1990's to 2001 for species related to shallow water and banks (50-150m) could reflect better coverage of these depths during the past decade. Changes from 2003 to 2004 could be influenced with the trawl door update from Greenland perfect to injector and may be species dependant, as no calibration experiments were made on this account. Index changes from 2004 to 2005 could be related to species specific data quality in the calibration experiments. If ignoring the calibration factors, the indices seems well connected for most species, indicating that there is little reason to calibrate in order to compare the timeseries. Indeed, even for Greenland halibut the length-dependent calibration factor has a 1:1 value around 12 cm which constitutes 80-90% of the individuals caught every year. Therefore, for the Greenland halibut abundance indices it matters little if calibrating or not.

Since the main purpose of the survey is to evaluate the biomass of northern shrimp and the effort is concentrated in areas and depths where the commercial shrimp trawling is taking place, especially on the northern slopes of the bank Store Hellefiskebanke (67°50N 55°00W) and in the inshore area Disko Bay. As Store Hellefiskebanke and Disko Bay are important nursery areas for Greenland halibut and redfish, as well as other important species (Smidt, 1969; Tåning, 1949) it is likely, that the abundance estimates of the survey reflects the juvenile stock situation of these species.

The 2002 estimates in division 1AN may have been affected by low coverage in this division, since only 2 hauls was performed in this division in 2002 and therefore not all strata can have been covered. No record exists on whether any compensation for low coverage was made in subarea 1AN in 2002.

2007. Strata 1C 50-100 no stations – area included in 1C 100-150.
2008. All strata surveyed.
2009. Strata 1A:50-100 no stations – area included in 1A 100-150.
2010. Strata 1A:50-100, 1A:100-150 no stations – area included in U1 150-200.
2011. Strata W1:400-600, C0:200-300, C0:300-400, C0:400-600 no stations - included in W1 300-400.
2012. Strata C0:200-300, C0:300-400, C0:400-600 no stations – area included in W1 300-400.
2013. Strata C0:400-600 no stations - included in C0 300-400. Strata W9:400-600 no stations – area included in W9 300-400.
2014. Strata C0:200-300, C0:300-400, C0:400-600 no stations – area included in W3 equivalent depth strata.
2015. Strata C0:200-300, C0:300-400, C0:400-600 no stations – area included in W3 equivalent depth strata. W1:400-600 included in W1 300-400. Northern area restricted to Eastern shelf due to sea ice.
2016. Strata C0:200-300, C0:300-400, C0:400-600 no stations – area included in W3 equivalent depth strata.

Table 2 - continued. Numbers of valid hauls in East Greenland since 2007.

East Greenland							
Year	Q1	Q2	Q3	Q4	Q5	Q6	Total
2007							35
2008	8	6	12	7	7	12	52
2009	21	12	26	19	6	13	97
2010	19	14	24	9	6	10	82
2011	20	11	21	12	7	14	85
2012	19	16	28	13	7	15	98
2013	25	12	22	14	5	14	92
2014	22	14	12	9	8	16	81
2015	26	11	24	12	8	14	95
2016	29	10	26	13	7	16	101

Note:
2007 Survey startup year. Only 35 hauls. No results presented.
2008. Strata Q1,Q2,Q4:0-200 no stations - included Strata Q1,Q2,Q3:200-400.
2009. Strata Q1:0-200 m no stations – area included in Q1:200-400.
2010. Strata Q1:0-200 m no stations – area included in Q1:200-400.
2011. Strata Q1:0-200 m no stations – area included in Q1:200-400.
2012. Strata Q1:0-200 m no stations – area included in Q1:200-400.
2013. Strata Q1:0-200 m no stations – area included in Q1:200-400. Strata Q5:0-200 m no stations – included in Q4:0-200.
2014. Strata Q1:0-200 m no stations – area included in Q1:200-400. Strata Q3:0-200included in Q4:0-200 (COD Q3:200-400.)
2015. Strata Q1:0-200 m no stations – area included in Q1:200-400. Stations in Icelandic EEZ included under strata in Grl.
2016. Strata Q1:0-200 m no stations – area included in Q1:200-400.

Table 3. Preliminary calibration factors to adjust the Cosmos trawl catches to the former Skjervoy trawl standard. For Greenland halibut and American plaice the conversion were length dependent and for those species x in the equations represents the individual fish length.

Fishspecies	Greenland halibut	Redfish	American plaice	Atlantic wolffish	Spotted wolffish	Cod	Thorny skate
Conversion factor	0.0404x+0.6527	2.4	-0.0825x + 5.3307	2.3	2.3	1.78	5.1
Trawl size factor	1/1.1516	1/1.1516	1/1.1516	1/1.1516	1/1.1516	1/1.1516	1/1.1516
Final factor	0.035x+0.567	2.0	-0.072x + 4.629	2.0	2.0	1.5	4.4

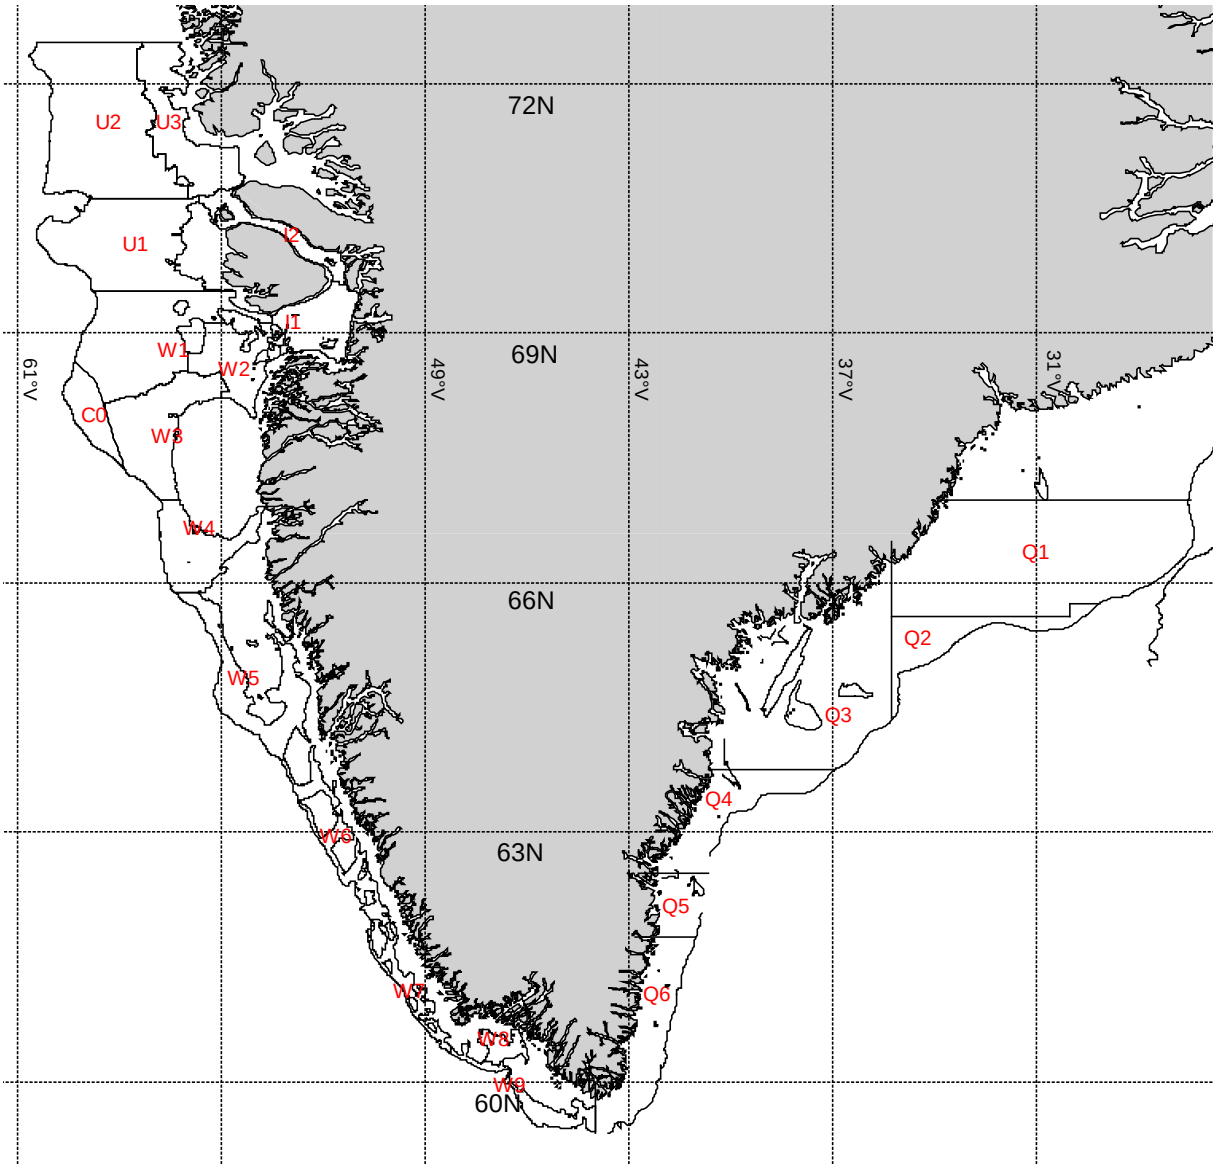

Fig 1. The Stratification areas used in the Greenland Shrimp and Fish survey. In West Greenland each strata is divided in depth strata of 150-200m. 200-300m. 300-400m and 400-600m. "Shallow" water strata of 0-100m and 100-150m delimited by the 3 nm line and the NAFO Div. Borders of the shallow water stratas are not shown. In East Greenland each strata is divided in depth strata of 200-400m and 400-600m. "Shallow" water strata of 0-200m is delimited by the 3 nm line.

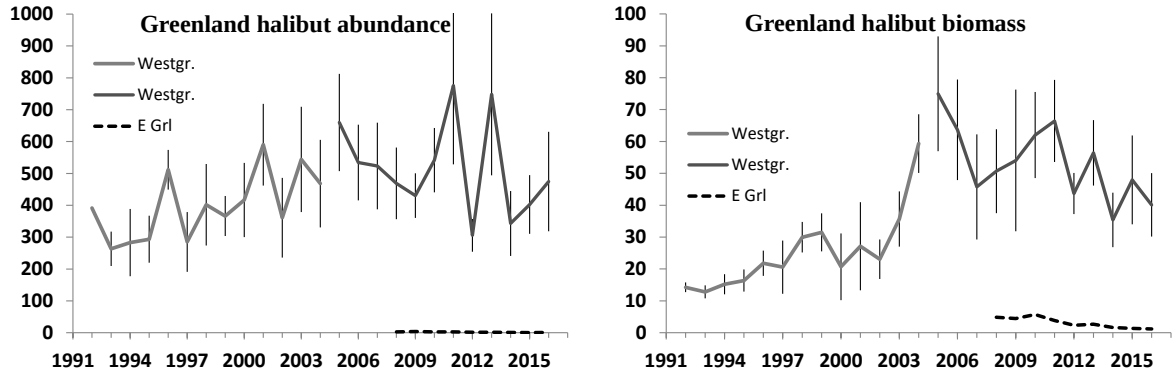

Fig 2. Greenland halibut abundance (million) and biomass (Kt) for West Greenland.

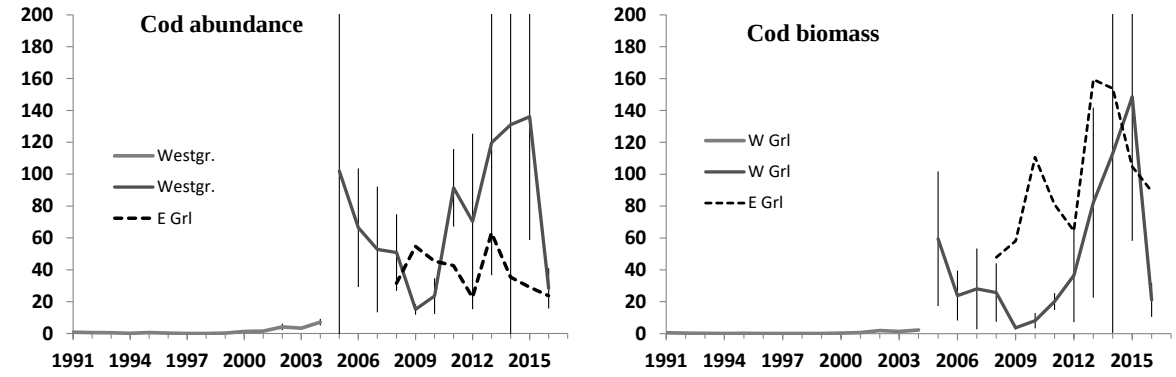

Fig 3. Atlantic cod abundance (million) and biomass (Kt) for West Greenland.

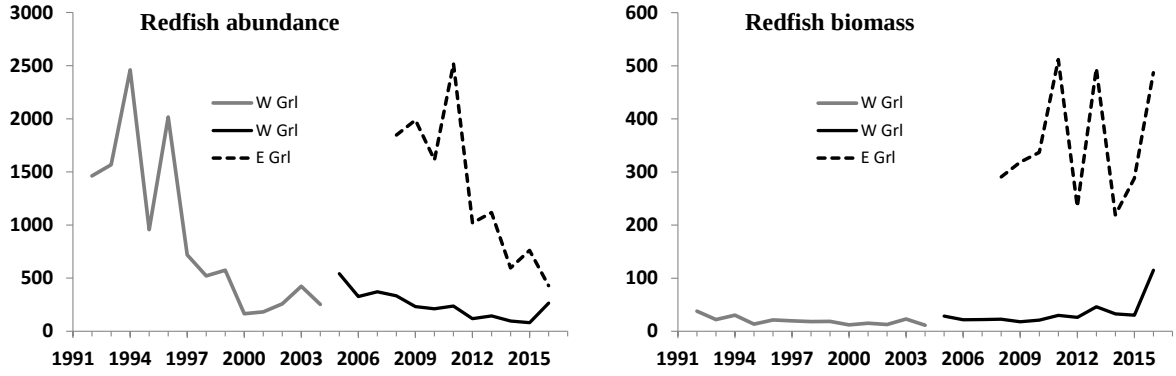

Fig 4a. Redfish species (*S. mentella* and *S. norvegicus* combined) abundance (million) and biomass (Kt) for West Greenland.

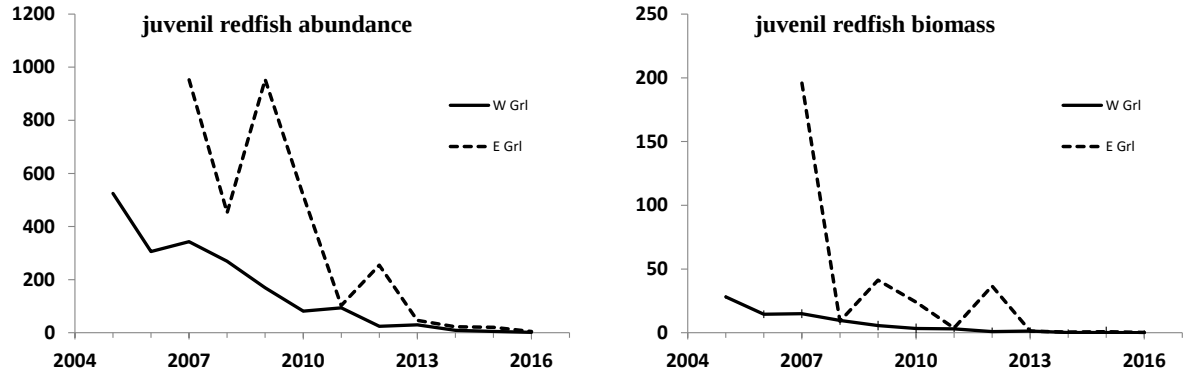

Fig 4b. Juvenil redfish >20 cm (*S. mentella* and *S. norvegicus* combined) abundance (million) and biomass (Kt).

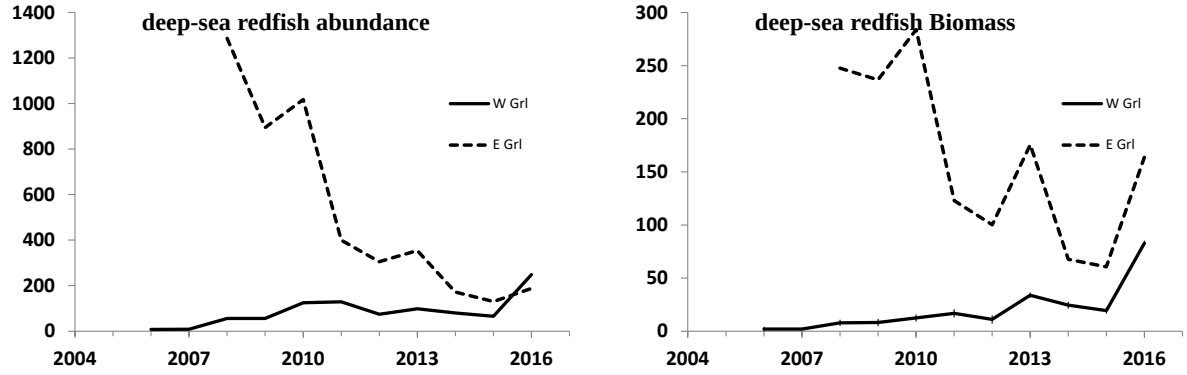

Fig 4c. Deep-sea redfish *S. mentella* abundance (million) and biomass (Kt).

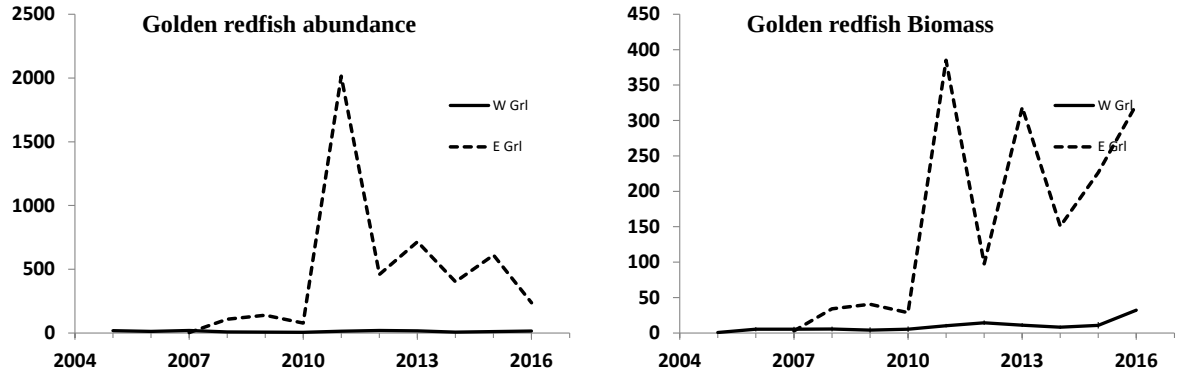

Fig 4d. Golden redfish *S. norvegicus* abundance (million) and biomass (Kt).

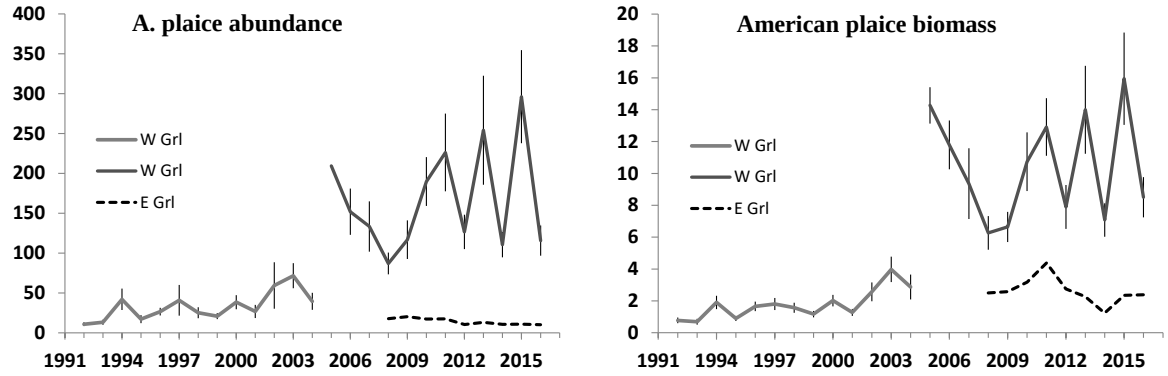

Fig 5. American plaice abundance (million) and biomass (Kt) for West Greenland.

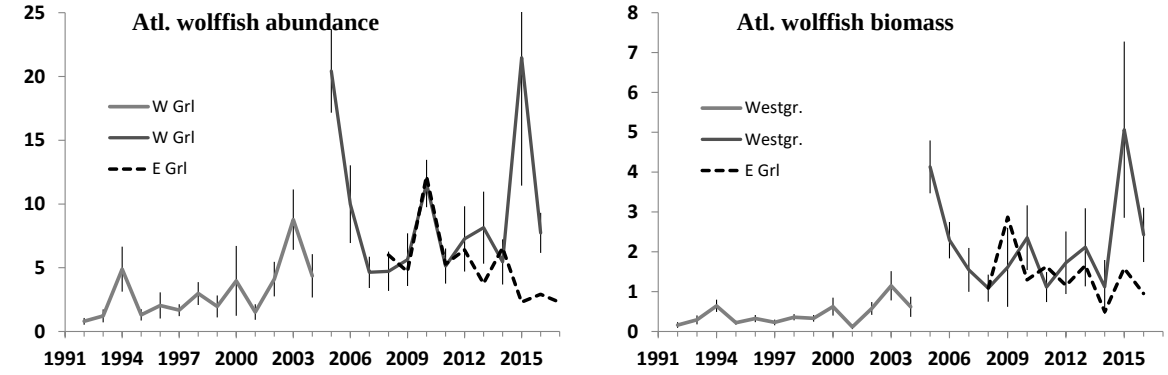

Fig 6. Atlantic wolffish abundance (million) and biomass (Kt) for West Greenland.

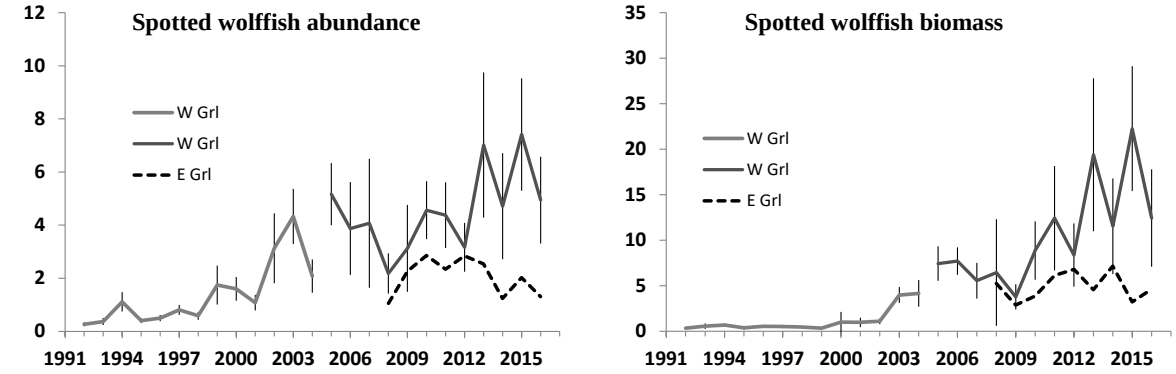

Fig 7. Spotted wolffish abundance (million) and biomass (Kt) for West Greenland.

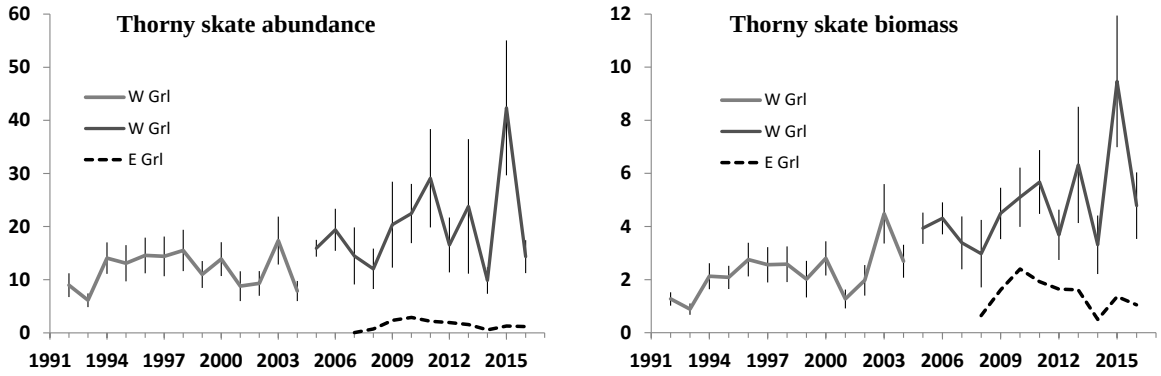

Fig 8. Thorny skate abundance (million) and biomass (Kt) for West Greenland.

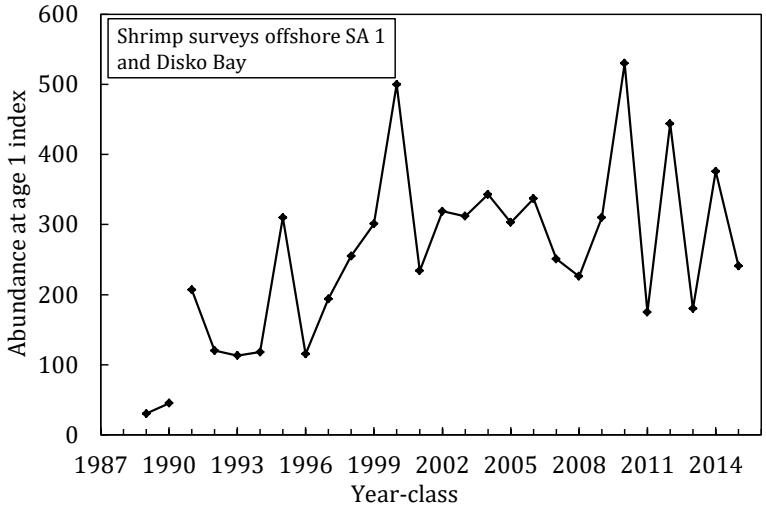

Fig 9. Total recruitment of age one including Disko Bay.

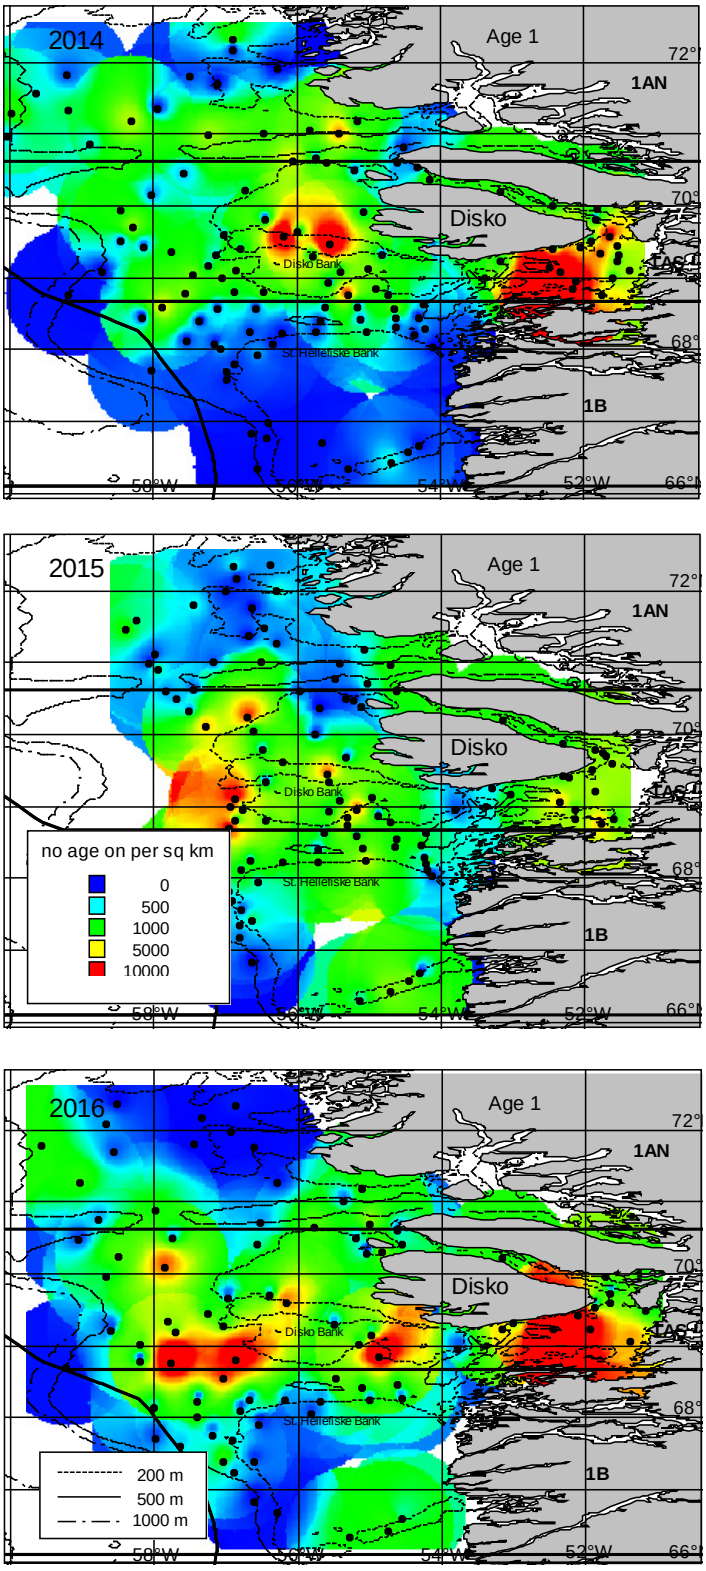

Fig 10. Distribution of one year old Greenland halibut in the 2014-2016 surveys.

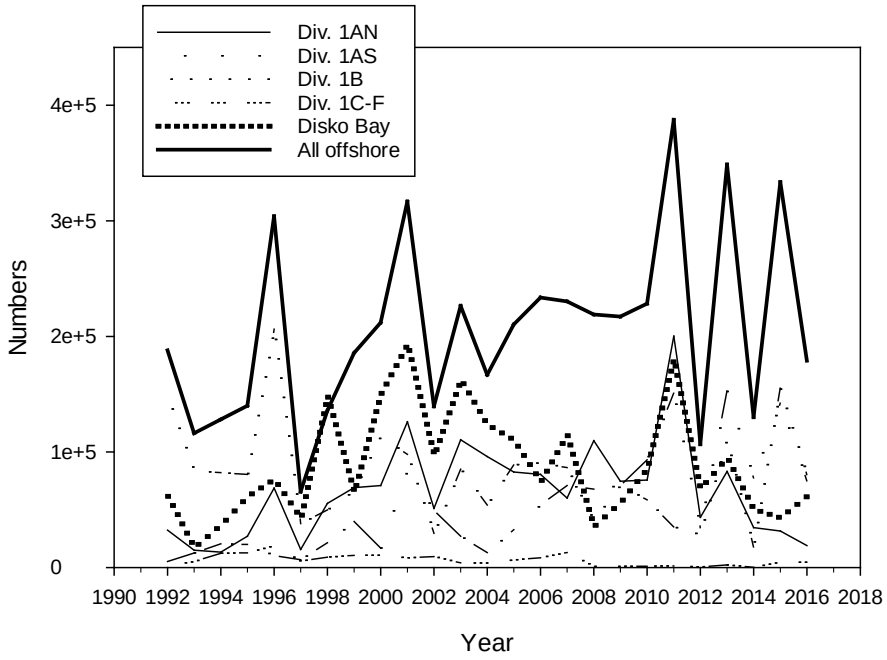

Fig 11. Number of one-year of Greenland halibut by division and year.

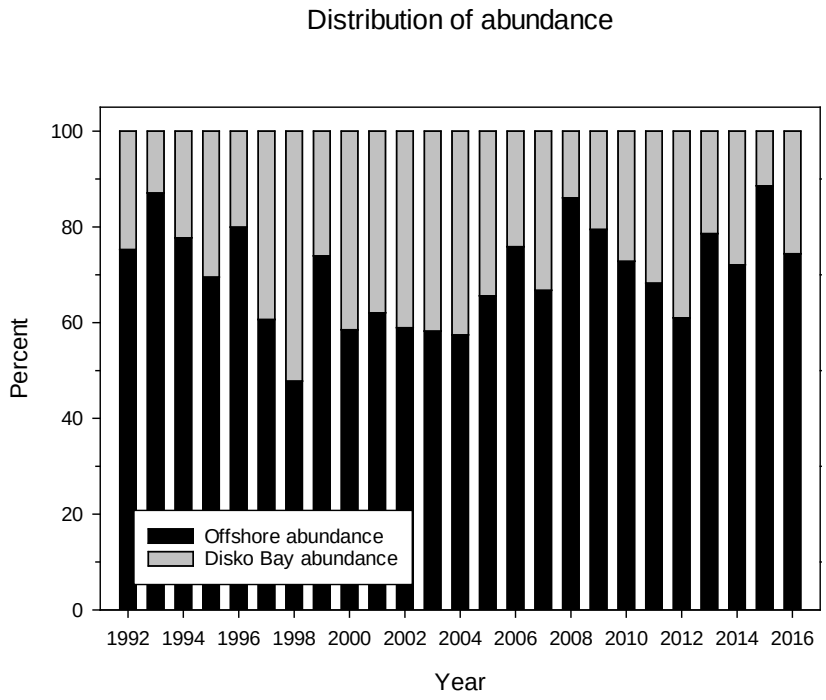

Fig 12. Relative distribution of one-year old Greenland halibut between offshore areas and inshore Disko Bay.

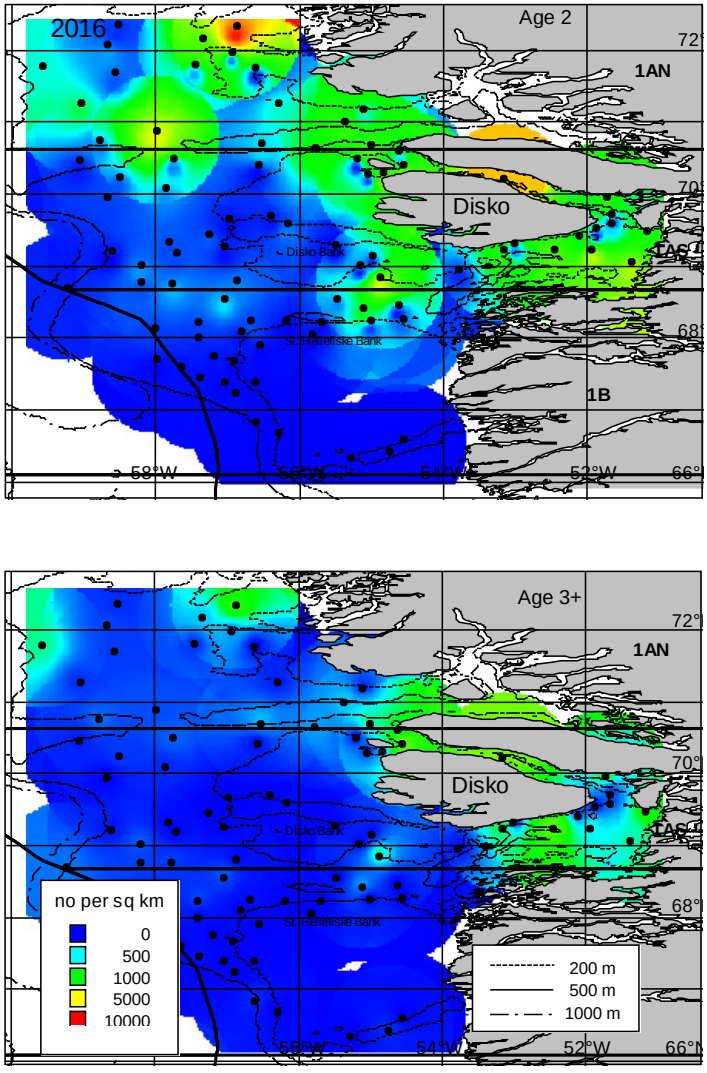

Fig. 13. Distribution of age 2 and 3+ Greenland halibut in the 2016 survey.

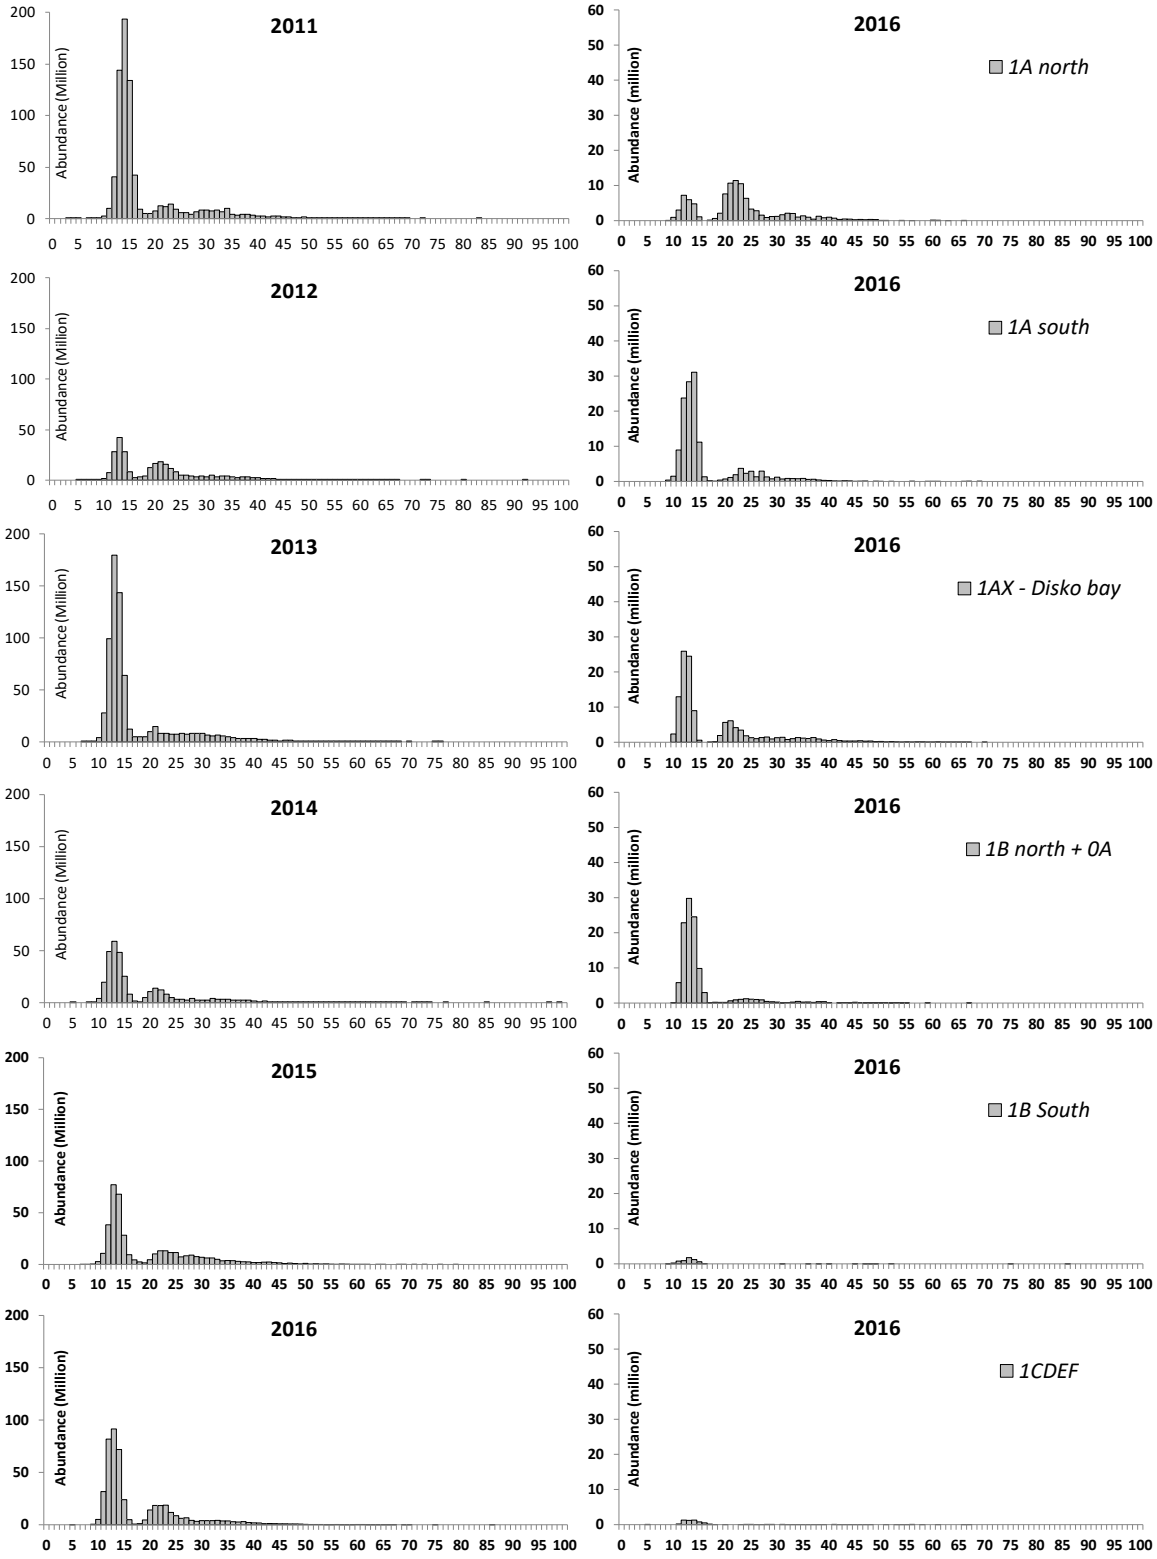

Fig. 14. Greenland halibut (*Reinhardtius hippoglossoides*). Length frequencies for West Greenland (left) and length frequencies per division (right).

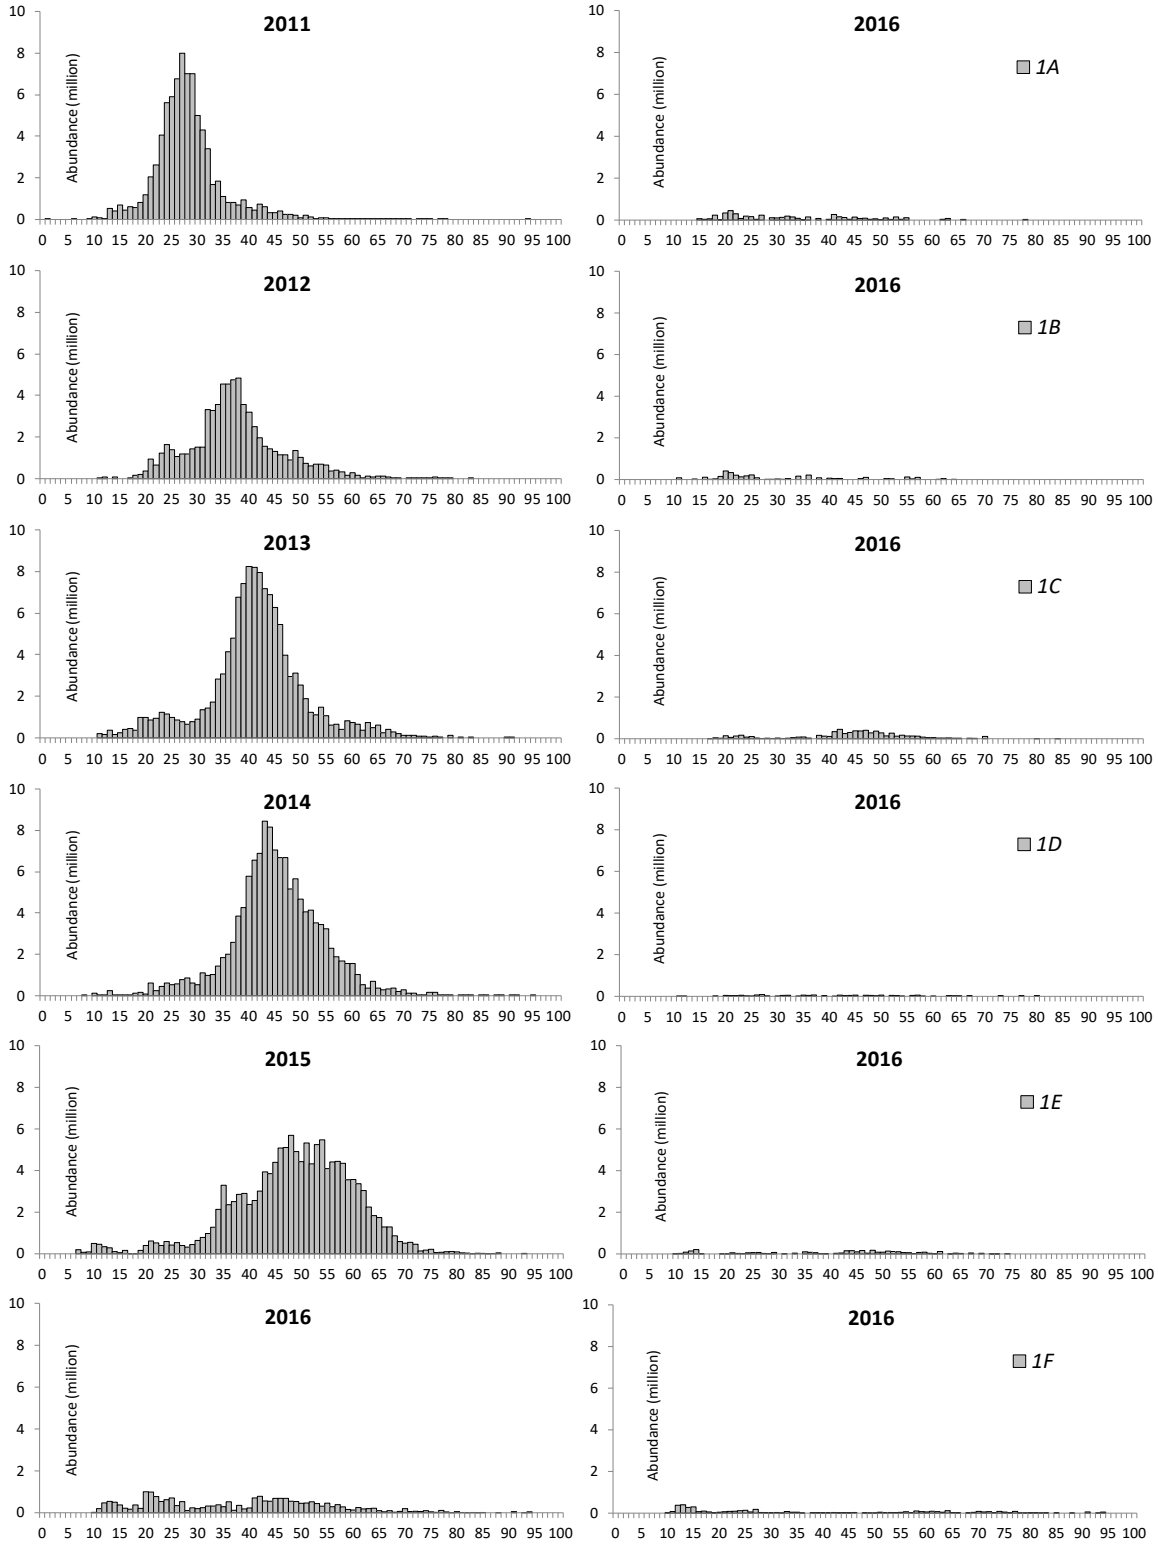

Fig. 15. Atlantic cod (*Gadus morhua*). Length frequencies for West Greenland (left) and length frequencies per division (right).

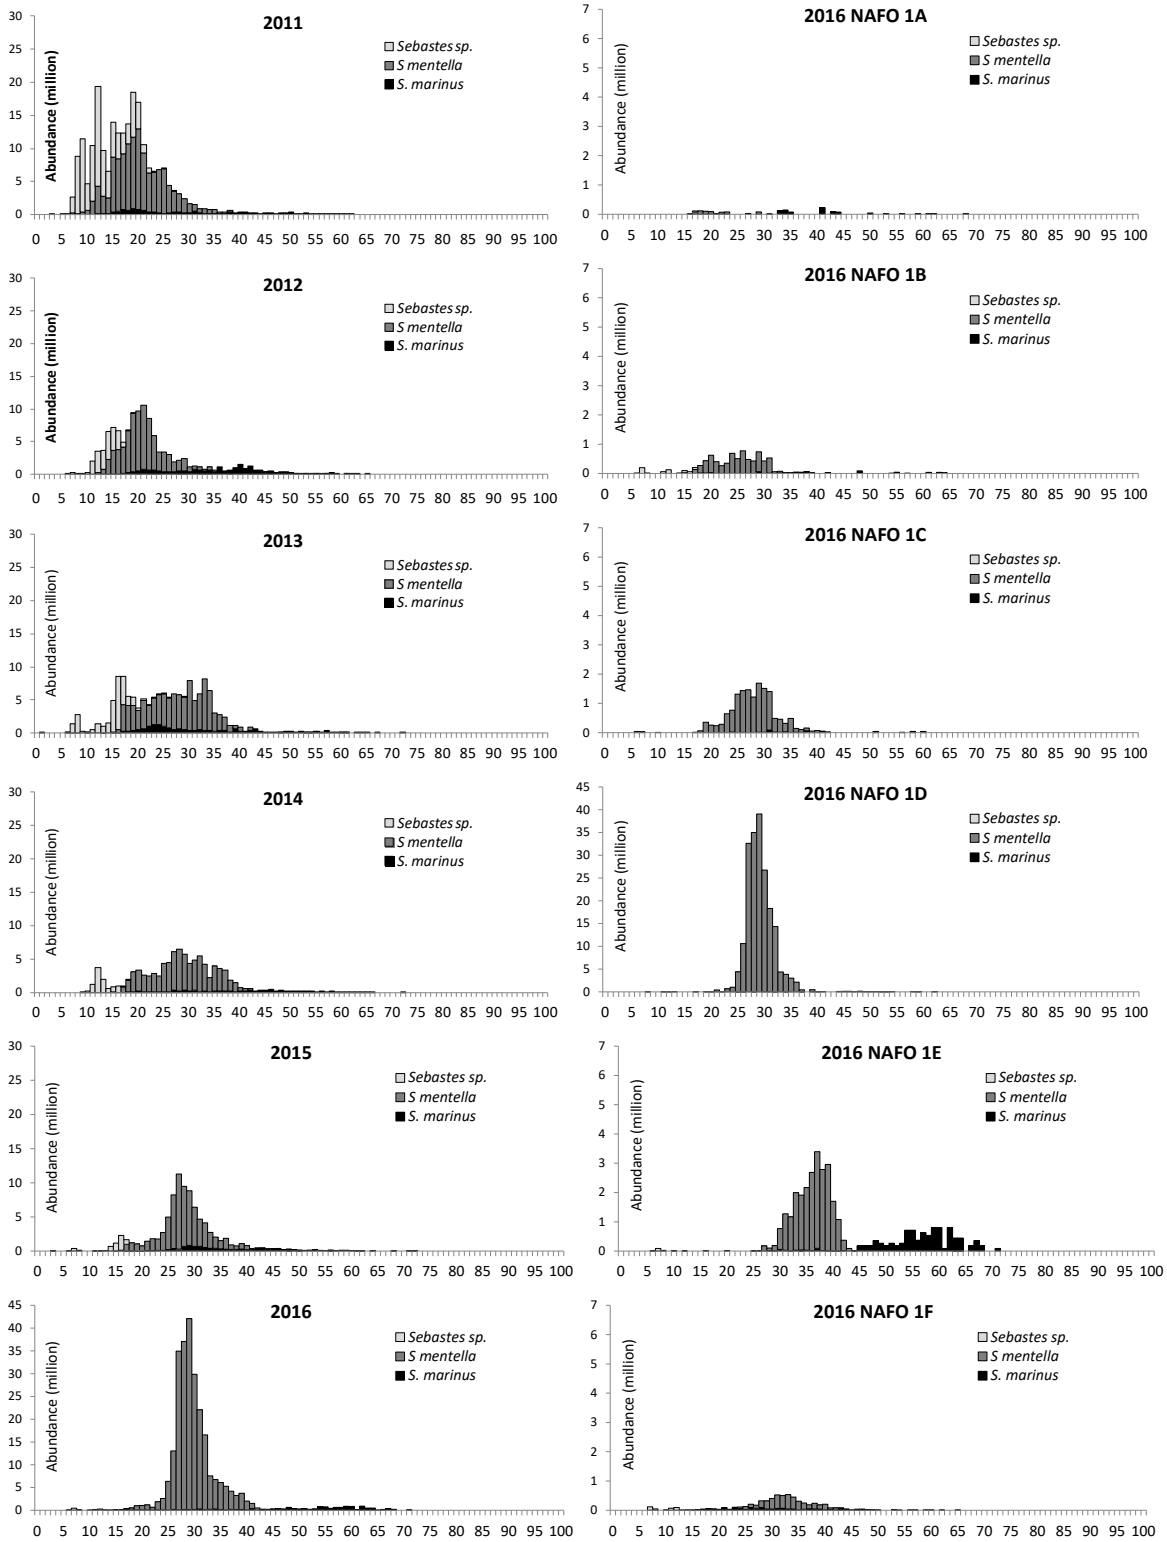

Fig. 16. Stacked Length frequencies for golden redfish (*Sebastes Norvegicus*), deep-sea redfish (Sebastes mentella) and juvenile redfish (Sebastes sp.) for West Greenland (left) and length frequencies per division (right).

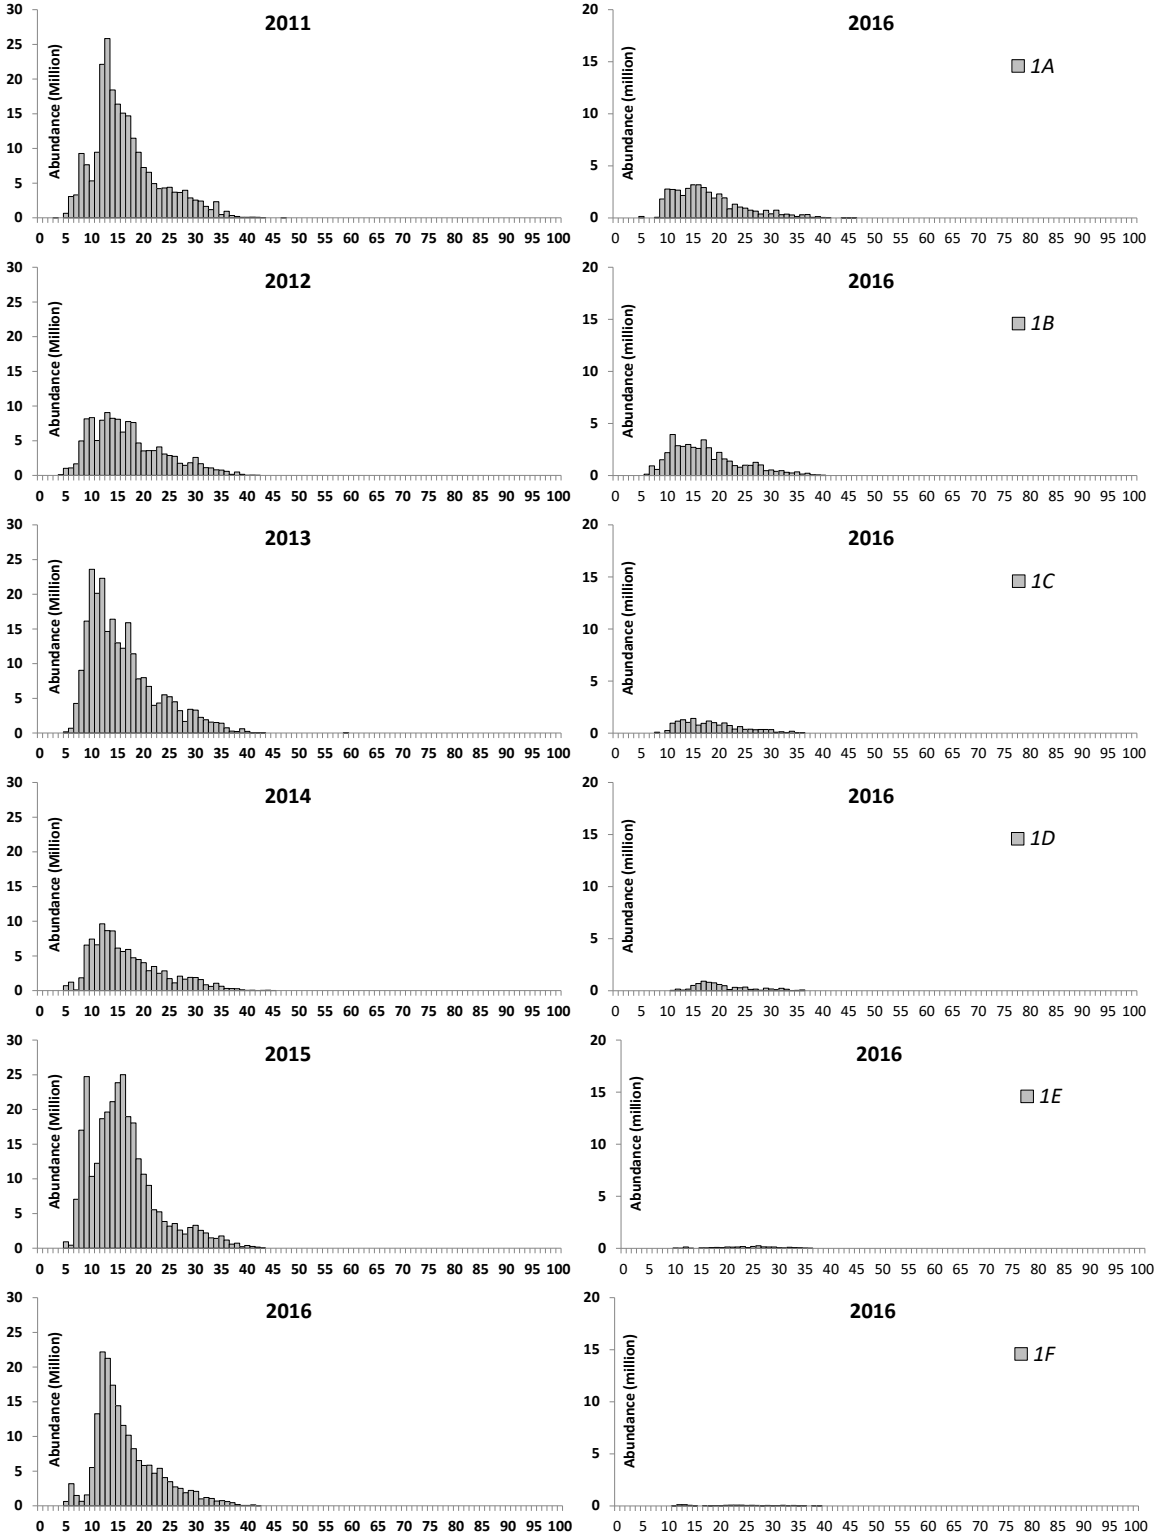

Fig. 17. American place (*Hippoglossoides platessoides*). Length frequencies for West Greenland (left) and length frequencies per division in (right).

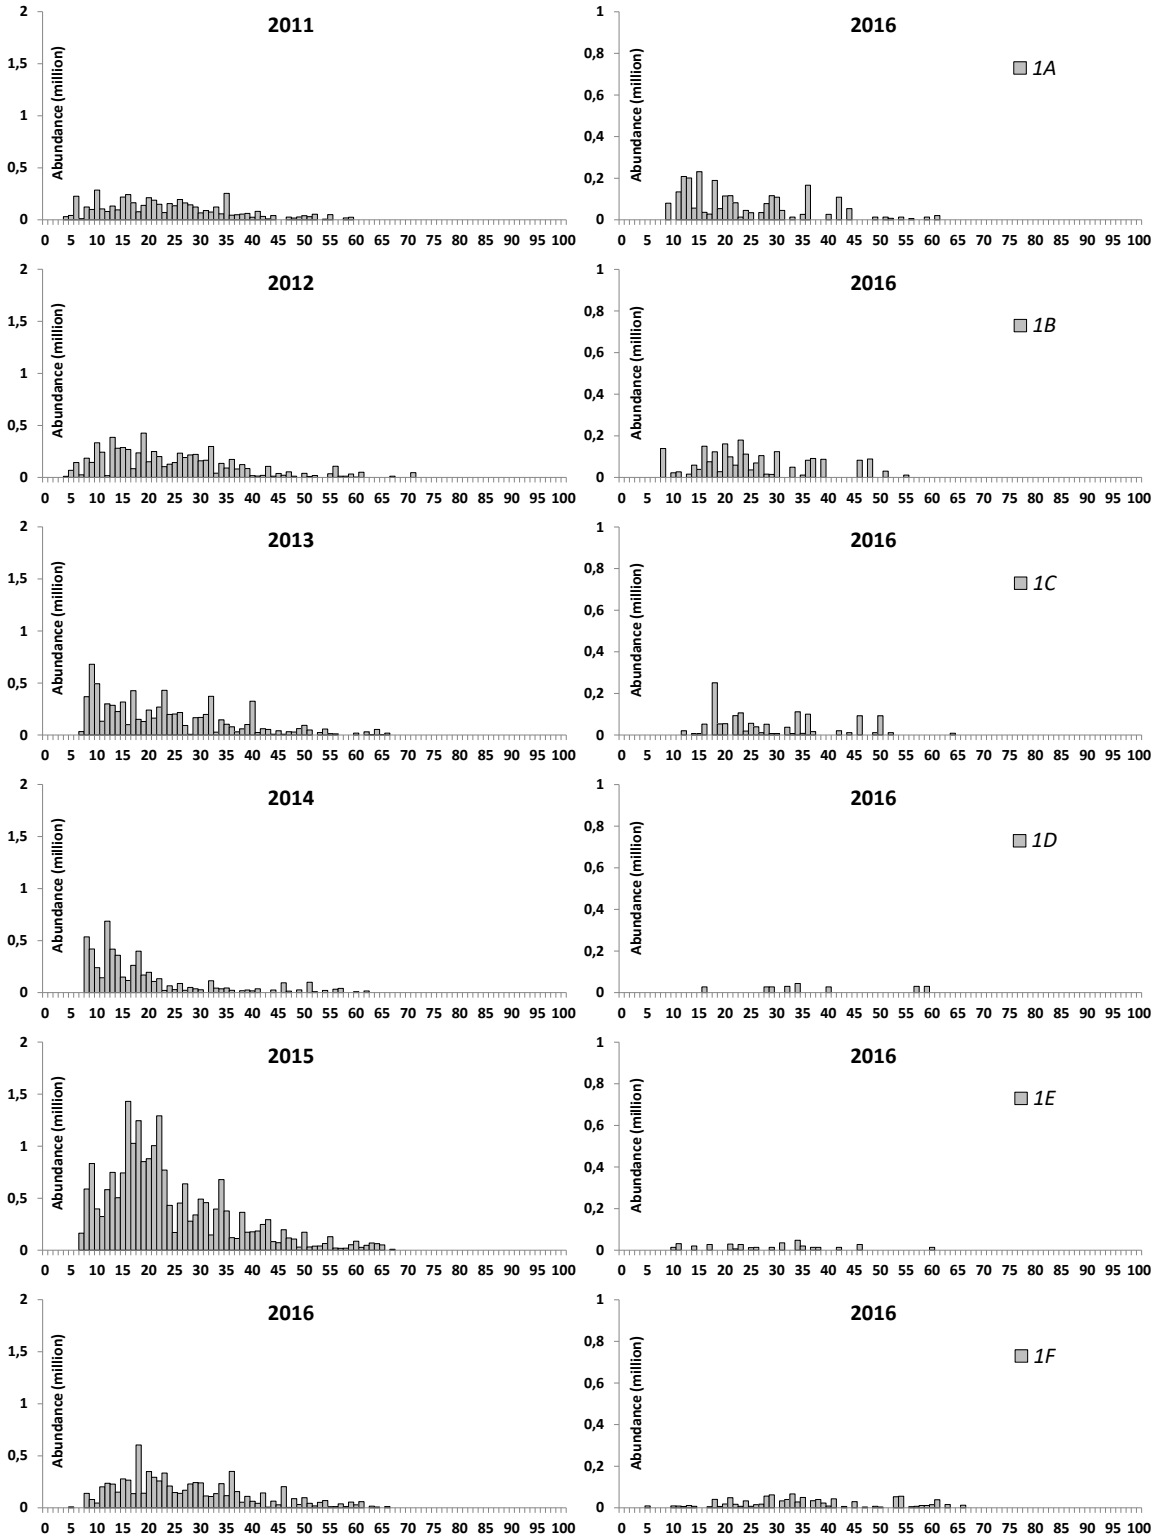

Fig. 18. Atlantic wolfish (*Anarhichas lupus*). Length frequencies for West Greenland by year (left) and length frequencies per division (right).

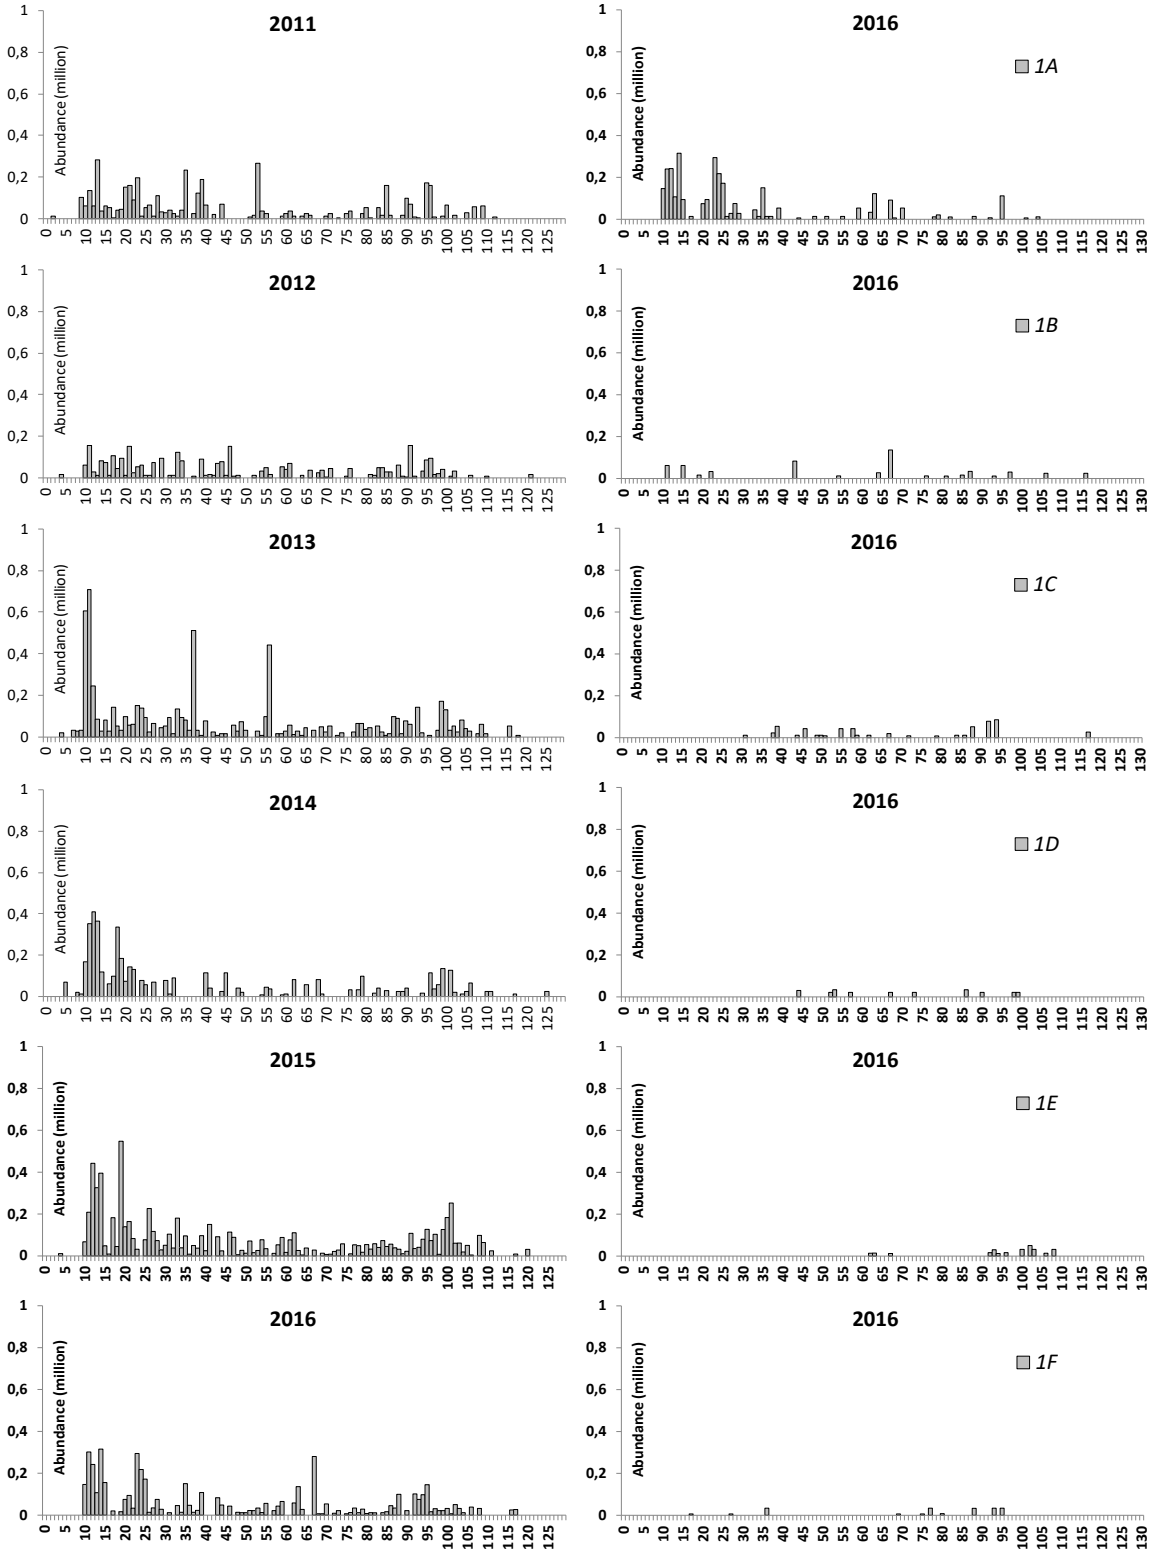

Fig. 19. Spotted wolfish (*Anarhichas minor*). Length frequencies for West Greenland (left) and length frequencies per division (right).

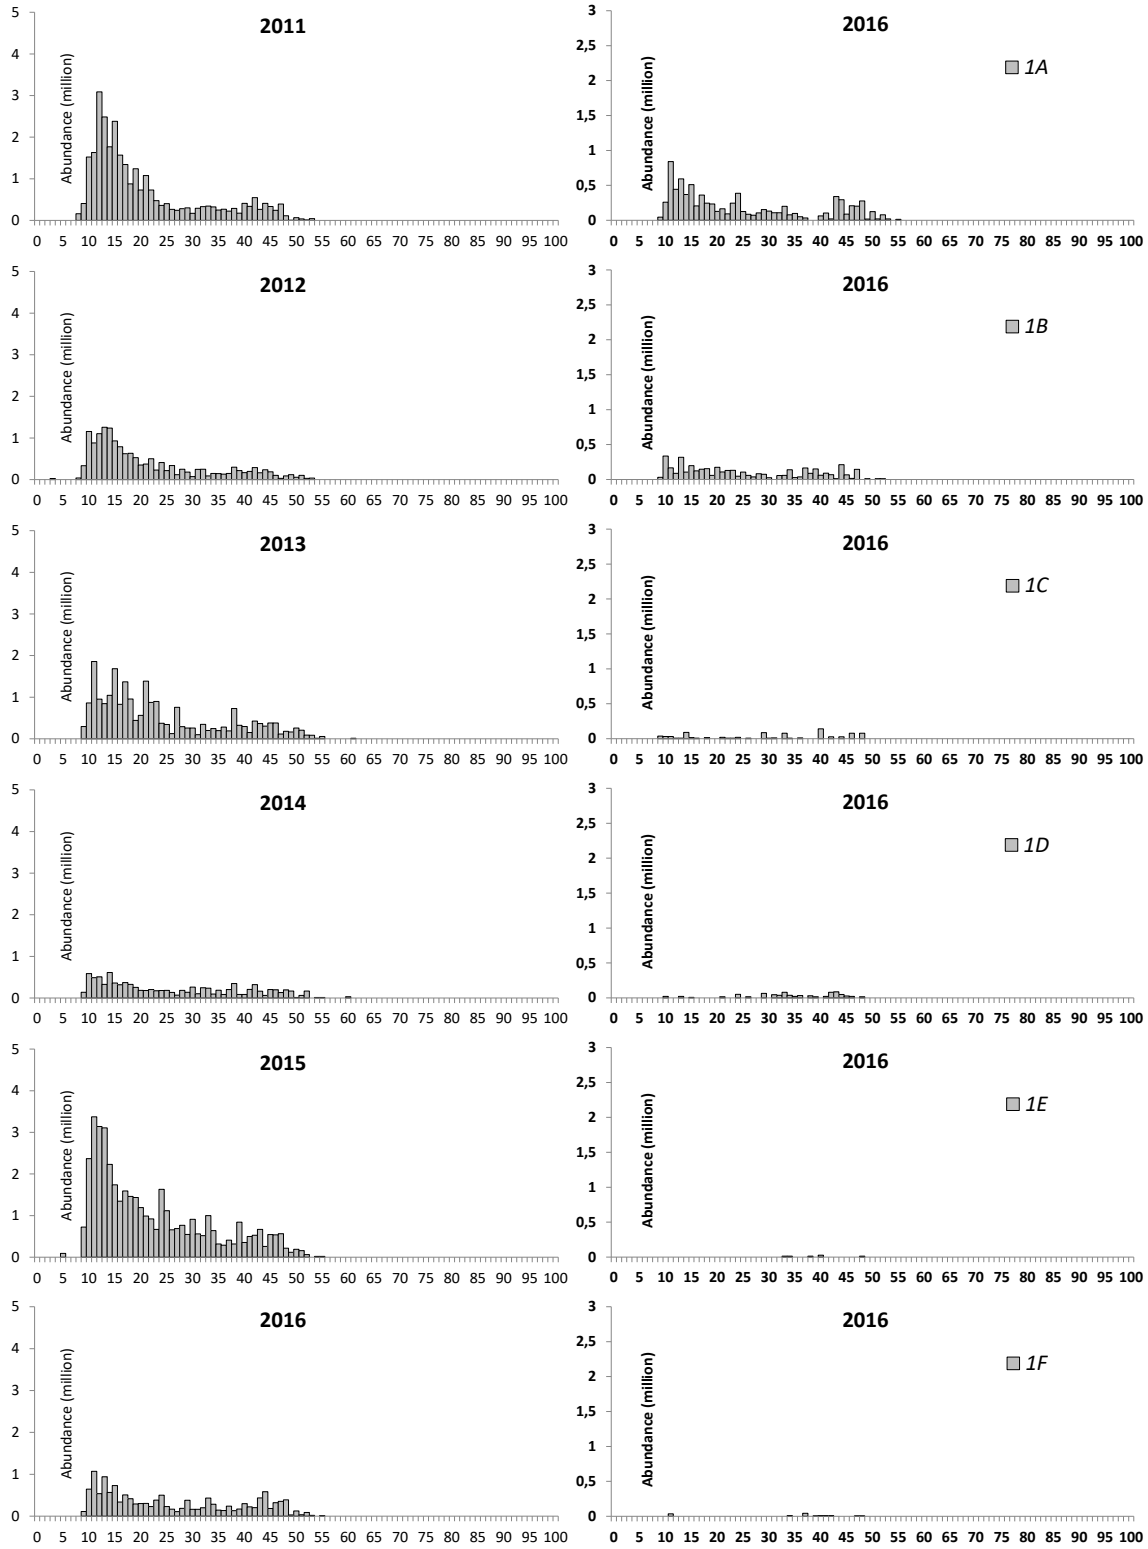

Fig. 20. Thorny skate (*Amblyraja radiata*) length frequencies for West Greenland (left) and length frequencies per division (right).
