# INTERNATIONAL COMMISSION <br> FOR THE NORTHWEST ATLANTIC FISHERIES 

# SAMPLING YEARBOOK 

Vol. 19
for the year
1974
(Revised)

Dartmouth • Canada
August 1978

## PREFACE

The ICNAF Sampling Yearbook has been issued annually since 1958 and has played a fundamental role in fish stock assessments carried out by the Assessments Subcommittee of STACRES. With the recent introduction of more rigorous sampling requirements and the greatly increased coverage of species and areas, the volume of sampling data has increased steadily with time. Consequently, the publication of the traditional volume of length and age frequencies and age-length keys was discontinued after Vol. 17 for 1972 and replaced by an annual listing of commercial and research sampling data contributed by member countries.

This issue of Sampling Yearbook is set out in four parts: Part 1 describes the ICNAF sampling requirements; Part 2 contains a list of countries which reported data for 1974 with notes on the data presented; Part 3 contains, in a series of tables arranged by species, lists of available 1974 sampling data pertaining to commercial fisheries; and Part 4 contains a list of research sampling data for 1974.

All available commercially-oriented sampling data for 1973 onwards have been computerized to provide for the rapid retrieval of data on computer printouts to meet specific requests. Copies of length frequencies, age-length keys and computed age frequencies (where applicable) will be forwarded upon request to institutions and/or individual scientists involved in the Commission's work. All requests should specify the actual sampling data required, indicating at least the species, country and division.

The Secretariat is grateful to those countries who have contributed sampling data and to those scientists who have continued to support the Commission's need for more adequate sampling of the Northwest Atlantic fisheries with a view to providing better assessments of the stocks.
V. M. Hodder

Assistant Executive Secretary

NOTE. This revised edition of Sampling Yearbook Vol. 19 for the year 1974 (previously issued in February 1976), became necessary following the receipt of additional data and amendments to existing data upon preparing the material for computer-processing.

## PART 1

## ICNAF Sampling Program

## 1. Introduction

In "A Fishery Research Program for the Northwest Atlantic", adopted by the Commission at its 1953 Annual Meeting (ICNAF Annu. Proc., Vol. 3, page 23), the need for catch sampling is emphasized as follows: "In order to recognize the effect of fishing, it is necessary to record the lengths of the fish in adequate samples of catches, showing fish discarded and fish retained. This is considered essential for all the fisheries for the important species by all the participating countries throughout the Convention Area. The total range of fish caught can be sampled only at sea by specially trained observers. The sea sampling of the sizes retained should be supplemented by sampling of landings ashore."

At its 1956 Annual Meeting, the Commission approved the following recommendation of the Standing Committee on Research and Statistics (STACRES): "For each species sampled, each country should report to the Secretariat the sizes, ages, weights and sexes of the fish sampled by place and time of capture. The Commission should publish these statistics" (ICNAF Annu. Proc., Vol. 6, page 11). The first issue of Sampling Yearbook was published in 1958, containing sampling data for the years 1955 and 1956. This was the beginning of the ICNAF sampling program.

During the years since the inception of the program, there have been many recommendations for improvements in relation to both the quantity and quality of the required data, and the need for full participation by member countries. In this volume of Sampling Yearbook, a first attempt was made to outline the present sampling requirements.

## 2. Minimum Sampling Requirements

At its 1974 Annual Meeting, STACRES reviewed several aspects of the sampling program. In reiterating the necessity for all member countries to adequately sample their commercial fisheries for length and age composition of catches, the minimum sampling requirement was revised to read as follows:
"That the ICNAF sampling requirement should be specified at one sample per 1,000 tons of fish caught for each division, quarter of year, and gear. As an approximate guideline, such samples should consist of 200 fish from the entire length range for length composition and one fish per centimeter length group for age composition."

Sampling data must be "in sufficient quantity and detail to enable the calculation of the length and age composition of the commercial catches by stock area on a monthiy basis" (ICNAF Redbook 1973, page 54). However, it is emphasized that the sampling data must be reported by division (or subdivision, where applicable) and not by stock area, in order to achieve uniformity in reporting and subsequent data-processing. Furthermore, in cases where the data for a species are required to be reported by sex, it is necessary that twice the number of specimens be collected for length and ageing in order to produce usable age-length keys.

The reported length frequency data should reflect the length composition of the catches made in each division (or subdivision) and month. Sampling should be more frequent when catches are high, and appropriate weighting should be applied to the individual samples to ensure that the monthly length frequencies represent the monthly catches.

## 3. Source of Sampling Data

In the past, sampling data have usually been classified as research, exploratory or commercial, depending on the type of fishing operations being undertaken at the time when the samples were collected. There has often been some confusion over the use of the terms, particularly in regard to the applicability of the various types of sampling data for assessment work, and some clarification is necessary.
a) Research. These samples are taken on true research vessels, operating independently of the commercial fishing fleet and using true research vessel fishing gear (e.g. otter trawl, with codend meshes considerably different from those in commercial trawls, or with codends lined or covered with small-meshed material irrespective of the mesh size of the codend). Because these
samples are not representative of commercial operations, they cannot be applied to the nominal catches, but are often of value for predicting future recruitment. Research samples are usually the outcome of survey programs to generate abundance and recruitment indices.
b) Commercial. Samples taken from the catches of exploratory and/or comercial fishing vessels using gear normally used for commercial fishing (in accordance with ICNAF trawl regulations, where applicable) should be classified as commercial samples. Such sampling implies that the escapement from the codend is not restricted by codend liners or topside covers or chafers and that the samples are representative of the commercial catches. These samples represent the commercial removals from the stocks and are essential for stock assessments.

In cases where samples are taken from the catches of research and/or exploratory vessels using commercial-type gears (e.g. trawls in which mesh selection is in accordance with the ICNAF mesh regulations), and where the fishing was carried out in association with commercial fishing operations, the data should be reported as "research vessel" data, with a note on the sampling form indicating the applicability of the data to commercial fishing (ICNAF Redbook 1977, page 67).

## 4. Sampling of Catches versus Landings

Commercial samples may be taken at sea from catches before any discarding has occurred (the term "discarding", as used here, implies fish thrown overboard and not included in the nominal catches, as opposed to fish used for fishmeal and included in the nominal catch), from catches after discarding, from landed catches at the dock or processing plant prior to discarding, or from landed catches after discarding. Thus commercial samples should be designated by type as follows:
a) Catch. The samples should be designated as catch samples, if it is fairly certain or definitely known that no discarding has occurred prior to sampling, whether the samples are taken from the catches at sea or taken from the landed catch at the dock or in the processing plant.
b) Landing. The samples should be designated as landing samples, whether they are taken at sea or in port, if it is known that discarding of small fish has occurred prior to sampling.
c) Discards. Every effort should be made to obtain representative samples of discarded fish, particularly in cases where the samples reported normally reflect the landings.

In some countries the only opportunity for sampling is of landings of fish that have been sorted into market categories (i.e. large, medium, and small). Samples taken in this way must be properly weighted (by the catch or landing for each category) and combined into a representative sample of the catch (or landings) prior to submission to ICNAF.

## 5. Length Sampling Data

Length measurements should always be taken of fish which are randomly sampled from the actual catches (or landings) and which are in the natural condition (round fresh fish). If the fish are measured in any other condition (e.g. gutted or dressed), necessitating the use of conversion factors, the appropriate conversion of the length measurements to those representative of "whole fresh" fish should be made before the length frequencies are reported to ICNAF.

At the 1975 Annual Meeting, there was some discussion on the proper length to be measured for the various species, i.e. fork length and total length (ICNAF Redbook 1975, page 79). In the light of evidence brought forward that the method of measuring differs among countries for the different species, it was strongly emphasized that information on measuring methods be reported by countries in their annual sampling notes. In order to ensure that the measuring method is recorded for all samples, it was recommended that provision be made on the standard sampling forms for countries to report the type of length measurement appropriate to the sampling data reported on the form. The revised forms (for soliciting 1975 and subsequent sampling data) provide for the recording of the various types of length measurements as follows:

Fork length - from the tip of the snout to the apex of the $V$ forming the fork of the tail, for species with forked tails.

Total length - from the tip of the snout to the tip of the longest lobe of the tail when the lobe is extended posteriorly in line with the body. This is sometimes referred to as greatest total length. For fishes with non-forked tails, only total length is appropriate.

Other (to be specified) - for example, mantle length for squids, upper valve greatest diameter for scallops, carapace length for shrimps, etc.

In addition to indicating the type of length measurement (as noted above), it is very important that countries provide the method of recording the measurements as follows:

Nearest cm (rounded) - measurements are recorded to the nearest centimeter (i.e. fish in the length range $29.5-30.4 \mathrm{~cm}$ are actually recorded as 30 cm ).

Cm below (truncated) - measurements are recorded to the centimeter below (i.e. fish in the length range $30.0-30.9 \mathrm{~cm}$ are recorded as 30 cm ).

Other (to be specified) - for example, capelin are to be measured in half-cm units, and should be recorded to the nearest half-cm or half-cm below.

## 6. Age Sampling Data

In order to assess the status of fish stocks by means of analytical models such as "Virtual Population" or "Cohort" analyses, realistic estimates of the age compositions of the catches are essential. The usual procedure is to collect substantial length composition data as being representative of the commercial catches of a species in a particular area over a given period of time. These data are supplemented by additional material for ageing, from which age-length keys are constructed. The representative length compositions are converted to age compositions by the application of the agelength keys to the length frequencies. These age composition estimates are then weighted by the catches to estimate the removals at age from the stock.

While the samples for length composition represent the basic sampling units, and these must be composed of fish randomly selected from the catches (or landings), samples taken to provide material for ageing may consist of fish which are randomly selected from the catches or which are selected by a stratified procedure:
a) Random sampling for age means that the sample is a random subsample of the length composition or it may be a separate small random sample of the catch taken specifically for ageing, with no attempt made to select fish by length groups.
b) Supplemented random sampling for age implies that the basic age sample was taken as in (a), but some effort is made to supplement the basic sample with fish in the upper and lower parts of the length frequency distribution in order to broaden the length spectrum of the age-length key.
c) Stratified sampling for age implies that a certain number of fish are selected from each length group represented in the catch length composition, and that the fish are selected at random within each length group.

Random age samples are the least effective of the three types, in that the number of specimens in each sample is usually only a fraction of the number of fish in the length sample, and consequently the entire range of the length groups represented by the catch length composition will rarely be covered. Thus ages cannot be properly assigned to those length groups in the length frequency where there are no ages in the corresponding length groups of the age-length key.

In contrast, stratified age samples are the most effective in that the length groups in the length frequency sample are usually also represented in the age-length key. This type of sample is also the most efficient in that the least number of fish are required to be taken for age determination.

## 7. Length Conversions

If the length measurements of fish taken for ageing are collected from specimens in the "round fresh" condition, the length groups in the length composition sample and those in the age-length key are directly comparable. If, on the other hand, the length composition sample consists of fish measured in the "round fresh" condition and the length measurements of the fish in the age sample are taken after the fish have been in frozen storage for a period of time, and, assuming that some shrinkage has occurred prior to measuring the frozen specimens, then the length intervals of the actual length composition data and of the age-length key are not directly comparable. The application of such an age-length key to the length composition data results in age compositions that are biased toward the higher age-groups. A very small shrinkage factor (say $3 \%$ ) can result in serious bias in the calculated age compositions. It is therefore extremely important that the length measurements of fish from frozen age samples be adjusted by appropriate conversion factors to make them representative of "round fresh" fish, if the actual length samples are measured when the fish are "round fresh".
8. Weight Conversions

As in catch statistics, the weights reported in sampling data are required to be round fresh weights. Any correction factors that may be required to convert gutted or otherwise dressed fish (including freezing) may be found in "Conversion Factors: North Atlantic Species, 1970. FAO Bull. Fish. Stat. No. 25".

The proper application of length frequency data to obtain the length composition of the catch require: that the average weight of fish in the sample be given. This value is readily obtained if the sample weight is recorded at the time the sample is collected. If length sampling is carried out at sea where weighing may be difficult or impossible, the average weight of the reported length frequency should be calculated by applying an appropriate length-weight relationship.

Calculating the mean weight from length-weight regressions must be done with consideration for the possible bias in incorrect appplication. It is not correct to obtain the mean weight by applying the mean length of fish in the sample to a length-weight regression based on measurements of individual fish. The result will be an underestimate of the mean weight and a consequent overestimate of the number of fish in the catch. The non-linearity of the length-weight regression must be taken into account and this is done by applying a vector of weights-at-length to the length frequency.

## 9. Sampling by Sex

Differences in growth rate and maximum length between the male and female of many species (e.g. flatfishes, hakes, redfish, capelin) require that the sex of the sampled fish be determined. Failure to discriminate sex in these species results in unrealistic age distributions. There are two ways to proceed, the first of which is recommended when feasible:
a) Each sex should be treated as an independent sampling unit; that is, length frequency data and ageing data are collected for male and female as if they were separate species. However, the sex ratio must be reflected in the length frequency total for each sex, so that the "per mille" frequency of male and female combined total 1000. The mean length and the mean weight should always be given for each sex and not just for sexes combined.
b) In cases where sex is difficult to recognize while collecting length frequency data, the alternative is to determine the sex when the individual fish constituting the age samples are being examined. In this case, it is important that the selection of fish at each length interval be random with respect to sex, in order to ensure that the sex ratio of fish at each length interval in the sample reflects the true sex ratio of the corresponding length in the catch. The resulting age-length keys (male and female separate) should upon application to the length frequency (male and female combined) result in age frequencies of males and females that are representative of the age compositions of the catches by sex.
10. Length Intervals and Sexing Criteria

At the 1974 Annual Meeting, the Statistics and Sampling Subcommittee reviewed the length groups to be used for the reporting of length frequencies and age-length keys, for most of the species sampled in the ICNAF Area, and specified the particular species for which it is essential that the data be provided by sex (males and females separately). The following list also includes changes agreed to at the 1975 Annual Meeting:

| Species | Length Group |
| :---: | :---: |
| Atlantic cod (Gadus morhua) | 3 cm |
| Pollock (=Saithe) (Pollachius virens) | 3. cm |
| Cusk (Brosme brosme) | 3 cm |
| White hake (Urophycis tenuis) | 3 cm |
| Wolffishes (Anarhichas sp.) | 3 cm (by sex) |
| Roundnose grenadier (Macrourus rupestris) | 3 cm (by sex) |
| Haddock (Melanogrammus aeglefinus) | 2 cm |
| Greenland cod (Gadus ogac) ... | 2 cm |
| Red hake (Urophycis chuss) | 2 cm (by sex) |
| American plaice (Hippoglossoides platessoides) | 2 cm (by sex) |
| Witch flounder (Glyptocephalus cynoglossus). | 2 cm (by sex) |
| Yellowtail flounder (SA 3-4) (Limanda ferruginea) | 2 cm (by sex) |
| Greenland halibut (Reinhardtius hippoglossoides) | 2 cm (by sex) |
| Winter flounder (Pseudopleuronectes americanus) | 2 cm (by sex) |
| Summer flounder (Paralichthys dentatus) ...... | 2 cm (by sex) |
| Redfish (Sebastes sp.) | 1 cm (by sex) |
| Silver hake (Merluccius bilinearis) ${ }^{1}$ | 1 cm (by sex) |
| Yellowtail flounder (SA 5-6) (Limanda ferruginea) | 1 cm (by sex) |
| Windowpane flounder (Scophthalmus Aquosus) | 1 cm (by sex) |
| Atlantic herring (Clupea harengus) | 1 cm |
| Atlantic mackerel (Scomber scombrus) ${ }^{2}$ | 1 cm |
| Atlantic butterfish (Peprilus triacanthus) | 1 cm |

| Species | Length Group |
| :---: | :---: |
| Alewife [Alosa pseudoharengus] | 1 cm |
| Atlantic argentine (Argentina silus) | 1 cm |
| Squids (Illex and Loligo) | 1 cm |
| Capelin (Mállotus villosus) | $\frac{1}{2} \mathrm{Cm}$ (by sex) |
| Sea scallops (Placopecten magellanicus) | $\frac{1}{2} \mathrm{~cm}$ |
| Northern deepwater prawn (Pandalus borealis) | 1 mm (by sex) |
| Other species not listed above should initially be reported by l-cm length groups. |  |
| At the 1975 Annual Meeting, it was recommended that silver hake be reported by 1-cm length groups and also by sex, instead of by $2-\mathrm{cm}$ length groups as in the past. Length frequencies not reported by sex must be supported by age-length keys for males and females separately. |  |
| At the 1975 Annual Meeting, it was recommended that length frequencies and age-1ength keys reported for mackerel be based on measuring the fork length to the centimeter below. |  |

11. ICNAF Sampling Forms (Rev. 01/77)

The completeness of the ICNAF data base, with regard to sampling data for the major commercial fisheries in the Northwest Atlantic, depends entirely on the extent to which member countries of ICNAF sample the catches of their fishing fleets and report these statistics to the Secretariat. As the ICNAF Sampling Program has gradually evolved over the years since its introduction in the early $1950^{\prime} s$, various types of forms have been adopted for use by member countries in reporting their sampling data to the Secretariat. More recently, with the need for standardization to facilitate computer-processing of the data, the basic information required has been consolidated into two forms, referred to as ICNAF Sampling Form 1 and Sampling Form 2.
a) Sampling Form 1 is designed for use in reporting sampling data for species for which both length and age data are available. For each quarter of the year and for each gear, division (or subdivision) and species, a separate sheet must be used. Three columns are provided for recording the "per mille" length frequencies by month within a quarter; it is very important that the applicable length group used be indicated. The main body of the sheet is for the age-length key for the quarter, expressed as the actual numbers of fish sampled for age (not on a "per mille" basis). The bottom section of the form is for providing the "per mille" age composition in each of the three months. The box in the lower right part of the form (number of age samples making up the age-length key) must be completed.
b) Sampling Form 2 is designed for use in reporting length compositions when no age data are available. The layout is similar to Sampling Form 1 except that more columns are provided for recording length frequencies.

For species which are required to be reported by sex, if both length and age data are available for male and female separately, use separate sheets of Sampling Form 1 for reporting the data for each sex. However, the sex ratio must be reflected in the length frequency total for each sex, so that the "per mille" frequency of male and female combined total 1000 . For example, if a length frequency consisted of 200 fish, of which 90 were male and 110 were female, then the frequencies recorded on the sampling sheets should total 450 for male and 550 for female, after applying the appropriate conversion factor.

If age-length keys are not normally available for certain species (e.g. squids), the monthly length frequencies (per mille) may be reported on Sampling Form 2. In the case of species required to be reported by sex, the frequencies for male and female should be recorded in adjacent columns of the same sheet and reflect the sex ratio as indicated in the preceding paragraph.

The details required below each length frequency on both Sampling Forms 1 and 2 must be as complete as possible. The "number of samples" (both length and age) and the "number of fish measured" must always be given, as these are used to assess the adequacy of sampling in relation to the minimum sampling requirements. While the mean length of fish in each length frequency can readily be calculated, the "mean weight of fish" in the length frequency is particularly important, as this is used as a weighting factor to estimate the length and age composition of the catch. This weight must, of course, be expressed as "round fresh" weight, as opposed to gutted or otherwise dressed weights. Information on "gear size" and "depth range" is often very useful in evaluating how applicable the sampling data reported are to commercial fishing operations.

INTERNATIONAL COMMISSION FOR THE NORTHWEST ATLANTIC FISHERIES AGE/LENGTH TABLE FOR SPECIES REPORTED IN 1-CM, 2-CM OR 3-CM LENGTH GROUPS

| Year: | Country: |  | Species: |  |
| :---: | :---: | :---: | :---: | :---: |
| Quarter: | Division (or Subdivision): | Gear: |  | Sex (where applicable): |
| Research, Exploratory or Commercial Fishing: |  | Catches or Landings: |  | Structure used for Ageing: |
| Check method of measuring fish | $\|$Fork 1ength $\square$ <br> Total 1ength | $\begin{array}{ll} \text { tle } \quad \square \\ \hline \end{array}$ | To nearest cm To cm below. | Reported by: |

AGE COMPOSITION (PER MILLE)

| Year: | Country: |  | Species: |  |
| :---: | :---: | :---: | :---: | :---: |
| Quarter : | $\begin{aligned} & \hline \text { Division (or } \\ & \text { Subdivision): } \end{aligned}$ | Gear: |  | Sex (where applicable): |
| Research, Exploratory or Conmercial Fishing: |  | Catches or Landings: |  |  |
| Check method of measuring fish ( $\sqrt{ }$ ) | Fork length Total length $\square$ | $\begin{aligned} & \text { tle } \quad \square \\ & \hline \end{aligned}$ | To nearest cm To cm below | $\left.\square\right\|_{\text {by: }} ^{\text {Reported }}$ |

NOTE: If reporting frequencies by sex, use groups of 3 columns above headed 'Ma1e', 'Females', and 'Total'.

Sampling Form 2 (Rev. 01/77)

## PART 2

## Notes on Sampling Data

## 1. Introduction

Sampling data reported to the Secretariat should be accompanied by notes on sampling procedures. These notes should contain descriptions of how the length and age samples are collected so that any limitations on the use of the data can be recognized and the correct interpretation applied. Information on the use of conversion factors (e.g. fork length to total length) and the method of determining the mean weight of fish in the samples is essential for the proper application of the data to stock assessment problems. However, in many cases, the sampling data were not accompanied by suitable descriptions of procedures used, and consequently the notes given in Section 4 below are in the main derived from information given in previous issues of the Yearbook.
2. Summary of Data Relevant to Commercial Fisheries

The following is a list of species and divisions for which commercially-oriented sampling data (see Part 3) were received from various countries for 1974:

| Country | Species | Divisions |
| :---: | :---: | :---: |
| Bulgaria | Atlantic mackerel | - 5Zw+6 |
| Canada (M) | Atlantic cod Haddock <br> Atlantic redfish <br> Pollock <br> American plaice <br> Witch flounder <br> Yellowtail flounder <br> Winter flounder <br> White hake <br> Atlantic herring <br> Atlantic mackerel | - 4R, 4T, 4Vn, 4Vs, 4W, 4X, 5Ze <br> - 4W, 4X, 5Ze <br> - 4R, 4S, 4T, 4Vn, 4Vs, 4W, 4X <br> - 4W, 4X, 5Ze <br> - 4R, 4T, 4V <br> - $4 \mathrm{~T}, 4 \mathrm{Vn}, 4 \mathrm{Vs}, 4 \mathrm{~W}$ <br> - 4Vs <br> - 4 T <br> - 4 X <br> - 4T, 4Vn, 4W, 4X, 5 Y <br> - 4T, 4Vn, 4W, 4X |

## 3. Summary of Research Vessel Sampling Data

The following is a list of species and divisions for which research vessel sampling data (see Part 4) were received from various countries for 1974:

| Country | Species | Divisions |
| :--- | :--- | :--- |
| Canada (Quebec) | Atlantic cod | $-4 T$ |
|  | Atlantic redfish | $-4 \mathrm{~S}, 4 \mathrm{~T}$ |
|  | American plaice | -4 T |

| Country | Species | Divisions |
| :---: | :---: | :---: |
| Denmark (G) | Atlantic redfish American plaice Greenland halibut Greenland cod Capelin | $\begin{aligned} & -0 B, 1 A, 1 C, 1 D \\ & -1 A, 1 C, 1 D \\ & -0 B, 1 A, 1 B, 1 C, 1 D \\ & -1 D, 10 \\ & -1 C, 1 D \end{aligned}$ |
| France (SP) | Atlantic redfish Atlantic herring | $\begin{aligned} & -3 \mathrm{Pn}, 3 \mathrm{Ps}, 4 \mathrm{R}, 4 \mathrm{Vn}, 4 \mathrm{Vs}, 4 \mathrm{~W}, 5 \mathrm{Ze} \\ & -4 \mathrm{Vn}, 5 \mathrm{Ze} \end{aligned}$ |
| Fed. Rep. Germany | Atlantic cod Atlantic redfish Polar cod | $\begin{aligned} & -2 \mathrm{~J} \\ & -2 \mathrm{~J} \\ & -2 \mathrm{~J} \end{aligned}$ |

## 4. Notes on Sampling Data

a) Bulgaria

No sampling notes were submitted for 1974. However, 1973 notes indicate that fork length measurements of mackerel are taken to the nearest millimeter and grouped in $1-\mathrm{cm}$ intervals, i.e. 30 cm includes lengths in the $30.0-30.9 \mathrm{~cm}$ range. Ages are determined from otoliths.

Data were submitted by P. Kolarov
b) Canada (Maritimes and Quebec)

Commercial landings in the provinces of New Brunswick, Nova Scotia and Prince Edward Island are sampled by the staff of the Biological Station, St. Andrews, N. B., in cooperation with the Conservation and Protection Branch and Fisheries Information Branch, all of which are agencies of the Fisheries and Marine Service of the Department of the Environment.

Landings of cod and haddock are normally culled by market category. Cod are divided into large (steak) and medium (market) categories at about 10 pounds fresh gutted weight. Small (scrod) cod and haddock are mainly less than $2-1 / 2$ pounds gutted weight. Small round haddock are sometimes landed in a separate market category. These market categories are usually sampled approximately in proportion to the relative numbers of each in the landing. When the final weighout is available, the length frequency of the landing is determined by applying weighting factors to each category. Length frequencies by sex are usually given for redfish, American plaice, yellowtail flounder, witch flounder and winter flounder.

Fork length measurements for groundfish are recorded to the nearest centimeter and for mackerel to the $1 / 2 \mathrm{~cm}$ below. For herring, the greatest total length (snout to longest caudal fin rays, with the caudal fin drawn in line with the body) is measured to the $1 / 2 \mathrm{~cm}$ below. For both herring and mackerel, the length frequencies are reported to the centimeter below, i.e. fish reported as 10 cm include those in the length range of $10.0-10.9 \mathrm{~cm}$. Mean lengths reported for herring and mackerel are adjusted upward by 0.5 cm . For groundfish, the length frequencies are reported in $1-\mathrm{cm}, 2-\mathrm{cm}$, or $3-\mathrm{cm}$ length groups as required.

Mesh sizes indicated are the manufacturers' specifications and hence are approximations to the actual mesh sizes. Hook size is given by number, No. $6 / 0$ being the smallest used commercially and No. 14 being the largest used on longliners in Quebec.

The codend mesh size is not measured at the time of sampling. The port technician records only that the mesh size is large or small. Redfish samples are usually from catches made with small mesh codends, approximately 64 to 88 mm. All other species are from catches made with large mesh nets, about 120 to 140 mm .

Otolith samples for ageing are taken for the major groundfish and pelagic species, and the data are reported in the form of quarterly age-length keys. Ageing material are not collected for redfish, and, although occasional otolith samples of such species as cusk and white hake are collected, these are not aged on a routine basis.

Some research (or exploratory) sampling data were reported by the Marine Institute of Quebec. The data consist of length frequencies of catches taken in small mesh trawls ( 80 mm ), but no notes on sampling methods were received.

Data were submitted by D. N. Fitzgerald, R. G. Halliday, J. P. Lussiaa-Berdou, D. S. Miller and W. T. Stobo.

## c) Canada (Newfoundland)

Length frequencies are based on samples obtained from landings of the commercial groundfish fishery. Measurements are recorded to the nearest centimeter for fork length of cod, haddock, and redfish and for total length of flounders (American plaice, witch, yellowtail, and Greenland halibut). The measurements are made on shore before any appreciable culling has occurred in the processing plants. Samples of commercial landings indicate that some of the catch may have been thrown away at sea prior to landing, whereas samples of commercial catches indicate that no fish was thrown away before landing. The length frequencies for each month are adjusted to the weight landed by each vessel before combining into monthly frequencies and converting to numbers per mille. The usual grouping was into $1-\mathrm{cm}, 2-\mathrm{cm}$, and $3-\mathrm{cm}$ length groups as required for the various species.

The age-length keys, used to calculate the monthly age frequencies from the monthly length frequencies, in most cases represent combined quarterly stratified otolith samples from the offshore fishery by the usual definition of quarters (i.e. Jan-Mar, etc). However, for some of the gears (i.e. longline, handline, codtrap, gillnets) used in the inshore fishery during the summer period, the age-length keys are derived from a large composite sample collected from all gears combined for a given division and time period. Also, the inshore length frequencies and age-length keys have been reported by fishing season rather than by quarter, i.e. Jun-Aug, in order to allow the combination of samples over the peak inshore fishing season. The various inshore gears used in coastal waters are operated on boats less than 50 GRT. All otter trawl samples pertain to offshore fisheries.

All mean weights are in kilograms and mean lengths in centimeters. Where sample weights were available, mean weights were calculated using these; otherwise, mean weights are estimated from length-weight relationships.

Length and age data for 1974 are reported for cod, American plaice, witch flounder, yellowtail flounder, and Greenland halibut. Length data only are reported for redfish. Otoliths are available for most of the redfish samples but the ageing has not been completed.

Data were submitted by P. Beck, G. Kean, A. T. Pinhorn and R. Wells.
d) Denmark (Faroes)

Sampling data for cod were reported for 1974, but no notes on sampling methods were received.
Data were submitted by K. Hoydal.
e) Denmark (Greenland)

All length measurements are total length to the centimeter below. Weights are given for whole, round fish. Samples other than those obtained on research vessels are supplied by local fishermen or obtained from the landings of trawlers. However, the method of having local fishermen supply samples on their own initiative is gradually being discontinued and the sampling of landings from the trawler fleet, which form a steadily increasing part of the total nominal catch by Denmark (G), is carried out by staff of the Research Institute.
The catches of trawlers are stored on board in boxes of $40-60 \mathrm{~kg}$ each, as head-on, gutted fish. Samples are taken, as the fish are being landed, by selecting at random a certain number of boxes. All fish in the boxes are measured, and a stratified sample of otoliths taken, normally 10 fish in each cm group where possible. Information on the total landed weight of each species by the vessel is obtained from the factory, and information on discards is obtained by interviewing the captain or other vessel personnel. The ship's log provides information on the areas fished during the trip.

Redfish, American plaice, and Greenland halibut were not measured by sex in 1974. This is mainly because these samples were obtained as research samples under conditions where higher priority is given to other species and where the limited manpower does not permit the time required for sex determination, but it is hoped that some sex-length keys will be available in the future. Some attempt was made to sex roundnose grenadier but it was found to be very difficult and many could not be categorized.

Age determination of redfish is virtually impossible, and also very difficult for Greenland halibut. For American plaice and roundnose grenadier some otoliths were sampled in 1974 but they have not yet been read. Also, ageing of these species seems difficult but a technique under development in the Rostock laboratory, GDR (for roundnose grenadier) will probably improve the situation. However, pending such possible results, for the time being our 1974 samples are reported as length samples only.

Since only limited quantities, if any, of American plaice and roundnose grenadier are landed commercially in Greenland, the only way of obtaining samples is by research vessels. For these two species it seems difficult to indicate comparison between the research samples and the commercial landings. Redfish and Greenland halibut are caught commercially. Redfish mainly as by-catch in trawl fisheries for cod and shrimp, Greenland halibut either in a directed fishery by longlines or sometimes trawl, or as a by-catch in trawl fisheries for cod and shrimp. The research samples are mainly obtained by small-meshed trawls and will, therefore, be comparable to the catch (but not landings) obtained as by-catch in the shrimp fishery but not to catches obtained by longlines or when trawling for cod or other species where the mesh size regulation applies.

In addition to the groundfish species for which sampling data are usually reported to the Secretariat, some length and age data on capelin (Mallotus villosus) from research catches in Div. IC and ID are also submitted. Data have also been collected (but not reported to ICNAF) on the deepsea shrimp (Pandalus borealis) from Div. IC, ID and IE ( 29 samples) and queen crab (Chionoecetes opilio) from Div. 1A, 1C and 1D (45 samples).

Data were submitted by Sv. Aa. Horsted.
f) France (M)

No sampling notes or sampling data were received for 1974.
g) France (St. Pierre and Miquelon)

While a substantial amount of sampling data from research vessel cruises were reported for 1974, no notes on sampling methods were provided.

Data were submitted by J. P. Bertome, D. Briand, P. DeCamps and A. Forest.
h) Federal Republic of Germany

No sampling notes were submitted with 1974 sampling data, but the 1973 notes indicate that length measurements are normally made of total length and recorded to the centimeter below. The length samples are normally collected at sea, but some samples were indicated as frozen, the shrinkage being 7 to 13 mm in the mean length (herring, Div. 5Z, September).

Data were submitted by J. Messtorff and A. Schumacher.
i) German Democratic Republic

No detailed sampling notes were submitted with 1974 sampling data, but it is indicated that herring are measured as total length and mackerel as fork length starting in 1974. Samples are usually measured at sea, but samples are sometimes collected by the ship's crews and frozen for later examination at the laboratory.

Data were submitted by W. Ranke.
j) Iceland

No fishing activity was reported in the ICNAF Area in 1974.
k) Italy

No sampling notes or sampling data were reported in 1974.

1) Japan

Samples were collected at sea from trawler catches and the specimens measured by the crew or by an inspector. Length measurements are made of the fork length to nearest millimeter for fishes with forked caudal fins and the total length for others. Mantle length is measured for squids. Redfish data have not been collected by sexes separately, but, in view of the need for this, attempts are being made to obtain measurements by sex. There are no age data for butterfish at present, but it is planned to collect materials for ageing in the near future.

Data were submitted by I. Ikeda and T. Sato.
m) Norway

Random samples of capelin were taken when the catches were delivered to the factory ship, usually one sample per day. All fish in the samples were measured and sexed. Length measurements were made of total length to the $1 / 2$ centimeter below. A stratified sample of otoliths was taken from the length sample, normally 5 fish in each $1 / 2$ centimeter group for each sex or all fish in the $1 / 2$ centimeter group if there were fewer than 5 fish.

Data were submitted by $\emptyset$. Ulltang.
n) Poland

No detailed notes were submitted with the 1974 sampling data. However, it was noted that samples are taken at sea on board of factory stern trawlers by a research team, and recently there have been attempts to have members of the trawler crews do some length measuring of fish. Herring and mackerel age-length keys are based on frozen samples, but it is unclear whether this also applies to other species.

Data were submitted by M. Giedz, J. Janesz, A. Kosior, M. Lipinski, A. Paciorkowski, E. Stanek and S. Ueinski.
o) Portugal

No sampling data or notes were received for 1974.
p) Romania

No sampling notes were submitted with the 1974 sampling data.
q) Spain

No detailed notes were submitted with the 1974 sampling data. However, it is noted that samples are collected at sea on board of a trawler. Age reading is done at the laboratory, each otolith being read by 3 readers and the age accepted when 2 of the readers agree.

Data were submitted by J. B. Fuertes, E. Labarta, M. G. Larraneta, E. Lopez-Veiga, J. Touron and A. Vasquez.
r) Union of Soviet Socialist Republics

No detailed notes were submitted with the 1974 sampling data. However, it is noted that length measurements are taken at sea, and otolith ageing done at the laboratory. Some samples designated as "R" (research) are taken on research or "scouting" vessels using commercial-sized gear. Silver hake otoliths are fixed in $96 \%$ alcohol or $60 \%$ glycerine, but the otoliths of other species are kept dry.

Data were submitted by K. G. Konstantinov, A. S. Noskov and A. P. Senina.
s) United Kingdom

No notes were submitted with the 1974 sampling data. However, as indicated in previous notes, length measurements are total length to the centimeter below and grouped into the length inter-
vals required for the various species. See Sampling Yearbook Vol. 18 for additional notes.
Data were submitted by B. W. Jones and C. L. Whiting.
t) United States of America

No sampling notes were received for 1974, but it was indicated that no changes in the sampling program had been made from the program of 1973. Dockside sampling is supplemented by sampling discards at sea. Sampling of discards is concentrated on yellowtail flounder. Scallops are sampled by measuring the top valves, which are saved by the crew from the last tow of a trip.

Data were submitted by R. K. Mayo, A. M. Tibbetts, G. T. Waring, P. Wood.

## PART 3

## List of Sampling Data for Commercial Fisheries, 1974

## 1. Introduction

The publication of detailed sampling data in the Sampling Yearbook was discontinued following the issue of Vol. 19 for the year 1972. Instead, as recommended by STACRES at the 1974 Annual Meeting (ICNAF Redbook 1974, page 70), the Yearbook now contains a list of available data, the details of which will be made available upon request to scientists and/or research institutes involved in the Commission's work.

Tables 1 to 26 contain lists of available length and age sampling data by species, each of which is arranged by country, division, gear and month. Nearly all of these data were reported as commercial samples. However, some samples reported as "research" have been included, where the type of gear used or the gear size reported indicated that they were relevant to commercial fishing operations. Sampling data relevant to pure research vessel operations (survey data not connected with commercial fisheries) are listed in Part 4 of this issue. Where sampling data have been reported by sex, the table entries under "Number measured" and "Number aged" indicate the numbers of males and females sampled.
2. Abbreviations Used

The following abbreviations are used to designate the "gear" and "type of sample" in Tables 1 to 26 and also in the listing of research samples in Part 4:

## GEAR

OTB - Bottom otter trawl (side and stern)
OTM - Midwater otter trawl (side and stern)
PTB - Bottom pair trawl (2 boats)
PTM - Midwater pair trawl (2 boats)
SN - Seine net (Danish and Scottish seines)
SB - Beach seines
PS - Purse seines
GN - Gillnets (set and drift)
LL - Longlines (set)
LHP - Handlines and pole-1ines
FPN - Uncovered pound nets
FWR - Weirs, barriers, fences, etc.
DRB - Boat dredges
NS - Gear not specified

TYPE OF SAMPLE
CC - Commercial catch
CL $\quad$ - Commercial landing
RC $\quad$ Research catch
RL $\quad$ Research landing

## PART 4

## Sampling Data from Research Vessel Surveys, 1974

The following table contains a list of available sampling data from research vessel surveys conducted in the ICNAF Area by certain countries in 1974. All of these data were reported as research vessel samples as indicated by the abbreviation "RC" under the heading "Type of Sample". The samples were reported as taken from catches retained in small-meshed codends or codends with small-meshed liners. In the case of some species (e.g. herring and mackerel) which are normally caught commercially with small-meshed trawls, both research and conmercial sampling data are listed in the previous section. The abbreviations for gears are defined on page 23.
