the Northwest Atlantic Fisheries

Serial No. 3839
(D.c.9)ICNAF Res.Doc. 76/VI/53ANNUAL MEETING - JUNE 1976Total trawl survey of bottom fishes in the Newfoundland area in 1975

by

V.A. Chekhova
PINRO, Murmansk, USSR**Abstract**

The paper presents the data on the abundance and biomass of principal commercial species in the Newfoundland area. The tabulated results characterize the distribution of fishes by depths and the size composition of various species in 1975, estimate the changes which occurred in the abundance and biomass of the species in the 1971 - 1975 period.

The total trawl survey of bottom species was made in June - September 1975 by R/V "Perseus III". The work was done according to a standard grid of stations with a bottom trawl whose bag was lined with a fine meshed capron net (knot to knot distance 8 mm) (Postolaky, 1972, Chekhova, 1975).

Investigations extended to 400 metres. Greenland halibut, witch and grenadiers who live chiefly below 400 m have not been included in our investigations. The data on the catches of these fishes at depths less than 400 m are to be found in tables 1 - 6.

The results of the survey are presented in tables 1 - 8. The supplement (tables 9 - 12) contains the data on the abundance and biomass of the principal commercial species by separate "strata" (Pinhorn and Pitt, 1972) in Divisions 3L, 3N, 3O, 3P_S. The present survey was made somewhat later than in the previous years - in July - September. In Division 3N the survey was carried out in two stages - in July and September - the interval between

the stages being 6 weeks (in tables pertaining to Division 3N the data for these two months are combined).

Discussion of results

The thorny skates. The indices of abundance and biomass of this species (catch in numbers and in kg per hour trawling) in all the years have been fluctuating insignificantly without any definite trend. A peak number of skates occurred at the depth of 100 - 200 m. In 1975 the young skates 12 - 20 cm long were reported from all Divisions. In Division 3P the thorny skates of 12 - 17 cm length made up 36% of the caught skates and in Division 3N they accounted for 33%.

The survey covered the areas of intensive fishing activities. One fact is of interest: in spite of the fact that the skates are the fishes living sedentary life, with a wide body and extremely low fecundity the removals during all the years have not in the slightest degree affected the abundance and size composition of the species.

The white hake. The white hake abundance and biomass for the last 5 years have been fluctuating.

From 1971 to 1973 in Divisions 30 and 3P was observed a marked decline in the abundance of white hake. A tendency toward an increase shown by the abundance and biomass first in 1974 continued in 1975. In 1975 in Division 3P most often were caught the fish of 42 - 50 cm length, in Division 30 - 21 - 26 cm long.

The haddock. The abundance and biomass of haddock on the southern slopes of the Grand Newfoundland Bank remains at a very low level. In Division 3N the haddock were caught only during two trawlings out of 40.41 specimens of 8 - 11 cm length were caught.

The cod. The soviet investigations have shown (Postolaky, 1962; Serebryakov, 1967) that in sub-area 2, Division 3K and the northern part of Division 3L there is a single cod stock.

The abundance and biomass of cod in Divisions 3K and 3L were fluctuating synchronously and these fluctuations were in a good agreement with the catches of the Soviet trawling fleet. The total trawl survey showed that the abundance and biomass of cod were at the highest level in 1972. Since 1973 the survey indices have sharply decreased and in 1975 were at a minimum level. A peak removal of cod was also in 1972 but from this year on it has been continuously decreasing.

In the catches taken in the course of the 1975 survey in Division 3K numerically prevailed the fish 24 - 29 cm long, in Division 3L - 27 - 38 cm long. The cod longer than 45 cm occurred in the catches in small numbers:

On the Flemish Cap Bank the abundance of cod began to increase in 1973 and the biomass - in 1974. In the last 2 years dominated the extremely strong 1973 year - class and the somewhat inferior in abundance but very strong 1974 year - class (USSR, Research Report, 1975). In 1975 the main cod concentrations kept at a depth 100 - 300 m. Most often were caught the fishes 21 - 35 cm long.

In Division 3N and 3O lives a single cod stock whose abundance and biomass have been declining from 1971 to 1973 but again have shown some increase from 1974 to 1975. In 1975 the cod kept at a depth 200 - 400 m.

On the St. Pierre Bank the abundance and biomass of cod have been decreasing since 1971 and in 1975 were at the lowest level. In 1975 the fish 12 - 17 cm long of the 1974 year - class at depths up to 100 m comprised 36% of the total number of specimens.

The golden redfish. The abundance of golden redfish in Divisions 3K, 3L, 3M in 1975 has decreased as compared with that of 1972 - 1974. In Division 3K the golden redfish of 6 - 13 cm length made up 48% of the total abundance.

The beaked redfish. In the period covered by the records of fish abundance and biomass the beaked redfish was the most abundant species in all ICNAF Divisions.

In Division 3E since 1971 the abundance and biomass of beaked redfish have not experienced significant changes. The fluctuations do not show any definite trend but one may say that in 1974 - 1975 the stocks of beaked redfish were at a rather high level.

Since 1972 due to the appearance of a number of strong year - classes (1963 - 1966 , 1967 - 1969) the abundance and biomass of the beaked redfish on the Flemish Cap have increased. In 1975 numerically and by weight small immature fish prevailed. The fish shorter than 30 cm comprised 68% of the stock.

The beaked redfish is most abundant on the southern slopes of the Grand Newfoundland Bank and on the St.Pierre Bank. The peaks of abundance were recorded in 1975. The fish longer than 30 cm accounted in Division 3N for only 1.4%, in Division 3O - 0.3%, in Division 3P - 0.0%.

The flat fishes. The abundance and biomass of the American plaice remain approximately at a stable level. In 1975 the abundance and biomass of the yellow tail flounder have shown a slight tendency toward a decline. Especially low in 1975 were the indices in Divisions 3L and 3P.
