the Northwest Atlantic Fisheries

Serial No. 5409

ICNAF Res. Doc. 79/VI/67

(Revised)

ANNUAL MEETING - JUNE 1979

Status of the Cod Stock in Divisions 3NO

by

C. A. Bishop and R. Wells
Newfoundland Environment Center
St. John's, Newfoundland, Canada

INTRODUCTION

Cod catches in Divisions 3NO which were restricted to a TAC of 15,000 tons, in 1978 have been as high as 227,000 tons (1967). This was considerably above the calculated MSY catch level of 100,000 tons, (Bishop and Wells, ICNAF Res. Doc. 78/VI/59). Catch rates (Spain PT-T.c.4) have declined from 1.7 tons per hour in 1967 to that of 0.2 tons per hour reported from the Spanish fishery in 1978. Catches in 1976 and 1977 of 24,283 and 14,700 tons were below the corresponding TAC's of 43,000 and 30,000 tons. The catch level at 2/3 F_{msy} effort was determined at 20,000 for 1978 and a TAC of 15,000 tons was set for 1978 to allow rapid rebuilding of the stock. The catch at 2/3 F_{msy} estimated using the catch and effort data up to 1977 was 25,000 tons.

Biomass estimates of cod in Divisions 3N and 30

Biomass estimates resulting from Canadian research surveys in 3N and 30 were calculated in a similar manner as abundance estimates presented in a previous paper (Bishop, ICNAF Res. Doc. 77/VI/17). The biomass estimates for 3N and 30 on a per mille basis for each year surveyed and for each estimating method used is shown in Tables 1 and 2. The results of a regression of Canadian (N) OT-(T.c.5) c/hr. on an average of the four methods is shown in Table 1 and Figure 1. The biomass values fluctuate over the period surveyed (1971-78) but are at present little different than those of the early 1970's.

A similar pattern of biomass estimates was found for Division 30 (Table 2). Data was available for fewer years than that for 3N and as such no regressions against CPUE are presented. Biomass values fluctuate but the recent values are not better than those of the early 70's.

Average abundance estimates in Numbers-at-age are shown in Tables 3 and 4. Only strata which had been fished in each of the years shown were compared. In both divisions there are indications that the 74 and 75 year-class may show some improvement over previous years.

Age composition in 1978.

The age composition derived for 1978 is shown in Table 5. Sampling data (frequencies and A/L Keys) were available from sampling of the Canadian commercial fishery for all four quarters in each of 3N and 30. The only other sampling data available were frequencies from three quarters from the Spanish fishery and one quarter from the gillnet fishery of Portugal. These were obtained through the Canadian operated Foreign Co-Operative Sampling unit and the frequencies obtained were adjusted using A/L keys from the Canadian sampling program.

Estimates of fishing mortality

Several methods were used to obtain an estimate of F which has been operating on the stock in recent years. Table 6 shows a regression of \ln of average catch per hour at-age against age using Canadian (N) (OT-T.c.5) as the effort standard. The value of F obtained was .50. Similarly Table 7 shows a regression using a 'standard' effort derived from combining all effort data available for 3NO. The F value derived was .59. Regressions were also obtained from the \ln of average per mille catch composition at-age for 1976-78 against age (Table 8) and from \ln of catch composition in 1978 against age (Table 9). The F values obtained were .47 and .54 respectively. Table 10 shows catch compositions for 1974-78 with survival rates calculated for ages 6-10 and 7-11 with the effort standard being that of Canadian N OT-5. The F value for the 1977-78 period was .77.

Research survey data from 3N and 30 in the form of average abundance estimates from strata surveyed in consecutive years were used to obtain estimates of F. Survival rates for the ages 6-10 and 7-11 were obtained and these are shown in Tables 3 and 4. The F for the 1977-78 period in 3N was .55 while that in 30 was .24. An average value from these seven estimates is .52 and as such a value of .50 was used in Cohort Analysis as the terminal F in 1978, (Table 11). The partial recruitment values used were obtained from a trial run using the estimated fishing mortality values for 1973-75 from ages 3-11. The estimated population values for 1978 indicate a declining stock.

Yield per recruit

Using the average lengths calculated from commercial cod sampling in 1978 and partial recruitment values used in the V.P.A. (Table 12) a yield per recruit curve was plotted (Figure 2). The F max value produced was 0.19. Pinhorn and Wells (ICNAF, Res. Doc. 11, 107-110, 1975) showed a similar yield per recruit curve with an F max value of 0.20.

Discussion

The biomass estimates from surveys showed some relationship with Canadian (N) C.P.U.E. ($r = .79$). However, there was little evidence of significant improvement in the biomass. Abundance estimates indicated that 1974 and 1975 year-classes may hold some promise. The 1978 catch composition (Table 5) showed that four and five year-olds made up the bulk of the catch with a significant number of three year-olds as well.

The fishing mortality (F) was estimated to be approximately 0.50 which was used in a V.P.A. run. This indicated that the stock has shown a steady decline to a level approximately 20% of that shown for the early 1970's. Values of F max from the yield per recruit showed that the F in 1978 of 0.50 was well above the F max of 0.19. It can also be shown that to catch the TAC for 1979 of 25,000 tons the stock will have to be (Table 13) fished at $F = 1.09$. Assuming an average recruitment of 25 million and fishing at F (max) 0.19, the catch in 1980 is projected to be between 5 and 6,000 tons (Table 4).

NOTE: Subsequent to the presentation of the original paper at the April 1979 Meeting of the Assessments Subcommittee, the Appendix which follows together with Tables 15-24 and Fig. 3 were added.

APPENDIX

Additional estimates of terminal F were obtained and the best estimate provided a basis for catch projections. From regressions of total F on effort using catch per unit effort data from Can. N-OT-T.c 5 and total F (F_4) at different values of F_t (Tables 15-18), it was shown (Table 19) that $F_t=0.35$ had a high predictive value of F_t in 1978. Figure 3 indicates the relationship of effort and F_t using Spanish PT-Tc. 4 and standardized efforts. The F_t values produced were 0.51 and 0.41 respectively. New stock sizes at age 3 were calculated for 1977, 78, and 79 (Table 20) from regressions of a USSR index at age 2 (in 3N) on VPA abundance values at age 3 for different values of F_t . At $F_t=0.35$ the values for 1977, 78, and 79 were 40.0, 40.8, and 18.9 millions respectively. An average value of 27 million was assumed for 1980. Assuming an F_t value of 0.35 in 1978 and a population size at age 3 as calculated for 1977, 78, 79, and 80, catch projections were obtained in 1980. It was assumed that a TAC of 25,000 t would be taken in 1979 and an F_t value of 0.19 in 1980. The results are indicated in Tables 21-24.

ACKNOWLEDGEMENTS

Mr. G.H. Winters and Mr. B. Vaske were kind enough to complete calculations necessary for Table 1, while Mr. A. Schumacker did those for Table 2.
