April 2016

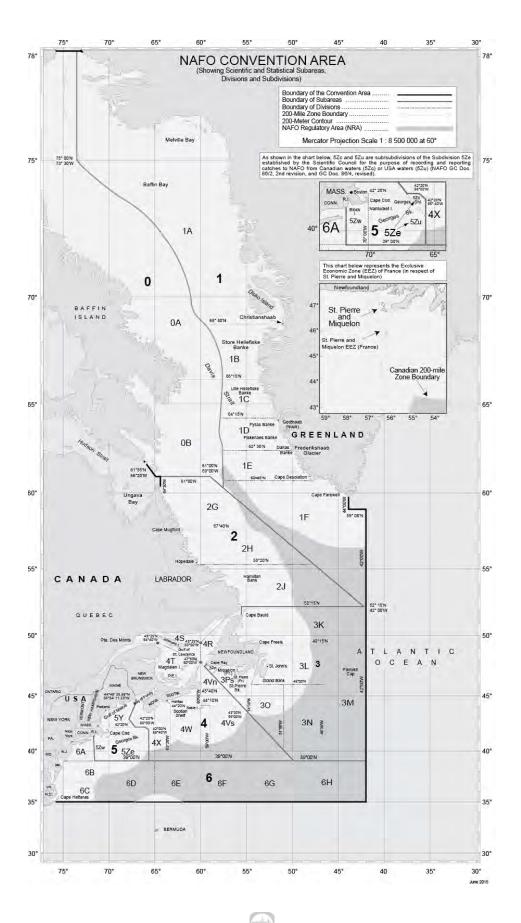

PREFACE

ii

This thirty-sixth issue of *NAFO Scientific Council Reports* containing reports of Scientific Council Meetings, as well as the Joint Fisheries Commission – Scientific Council Meetings held in 2015, is compiled in ten sections: **Part A** – Fisheries Commission and Scientific Council *ad hoc* Working Group on Catch Reporting, 20-21 April 2015; **Part B** – Fisheries Commission and Scientific Council Joint Working Group on Risk-Based Management Strategies, 22-24 April 2015; **Part C** – Scientific Council Meeting, 29 May – 11 June 2015; **Part D** – Fisheries Commission and Scientific Council Meeting, 29 May – 11 June 2015; **Part D** – Fisheries Commission and Scientific Council Meeting, 9 May – 11 June 2015; **Part D** – Fisheries Management(WG-EAFFM), 15-17 July 2015; **Part E** – Scientific Council Meeting, 9- 16 September 2015; **Part F**–NAFO/ICES *Pandalus* Assessment Group (NIPAG) Meeting, 9–16 September 2015; **Part G** – Scientific Council Meeting, 21-25 September 2015; and **Part H**– the Agendas, Lists of Research and Summary Documents, List of Representatives, Advisers, Experts and Observers, Merit Awards and List of Recommendations relevant to Parts A-I.

For annexes to the Fisheries Commission and Scientific Council Joint Working Group on Catch Reporting (Part A), Fisheries Commission and Scientific Council Joint Working Group on Risk-Based Management Strategies (Part B) and the Fisheries Commission and Scientific Council Joint Working Group on the Ecosystem Approach Framework to Fisheries Management (Part D), see the original meeting reports, available from the NAFO website.

Report of the Fisheries Commission and Scientific Council *Ad hoc* Working Group on Catch Reporting (NAFO FC-SC Doc. 15/01)

3

20-21 April 2015

1. Opening

The Working Group co-Chairs Sylvie Lapointe (Fisheries Commission Chair) and Don Stansbury (Scientific Council Chair) opened the meeting at 1000 hrs on Monday, 20 April 2015 at the NAFO Headquarters in Dartmouth, Nova Scotia, Canada.

Representatives from Canada, Denmark (in respect of the Faroe Islands and Greenland), European Union, Norway, the Russian Federation and USA were in attendance (Part H, this volume).

2. Appointment of Rapporteur

Neil Campbell and Ricardo Federizon of the NAFO Secretariat were appointed co-Rapporteurs.

3. Adoption of Agenda

The agenda as previously circulated was adopted (Part H, this volume).

4. Review of Status of the WG Recommendations from the February 2014 Meeting

The recommendations, documented in FC-SC Doc. 14/01, were adopted by the Scientific Council (SC) during the Scientific Council Meeting held June 2015 in Halifax, Nova Scotia and the Fisheries Commission (FC) during the 36th NAFO Annual Meeting held September 2014 in Vigo, Spain. A broad recommendation is the establishment of a process for catch estimation using a suite of available data housed at the NAFO Secretariat and any other available data.

In addressing this recommendation, a framework for the validation of the NAFO catch data and generation of catch estimates was discussed (see agenda item 5).

5. Development of a framework for the validation of NAFO catch data and generation of catch estimates

A review of the available NAFO fisheries catch databases housed at the Secretariat was conducted. The catch databases (metadata) in their current form and contents, as well as other sources such as dockside monitoring, were evaluated in terms of their potential usefulness and limitations in catch estimation and validation. The tabulated evaluation would be considered a "living document" as it would be used as a guide and would be regularly reviewed and updated during the exercise of catch estimation and validation (see Appendix of Annex 3, NAFO FC-SC Doc. 15/01).

It was noted that among the NAFO data sources, the VMS and CAT database and the haul-by-haul logbook data information are considered the primary source for catch validation information, the latter also for effort validation information.

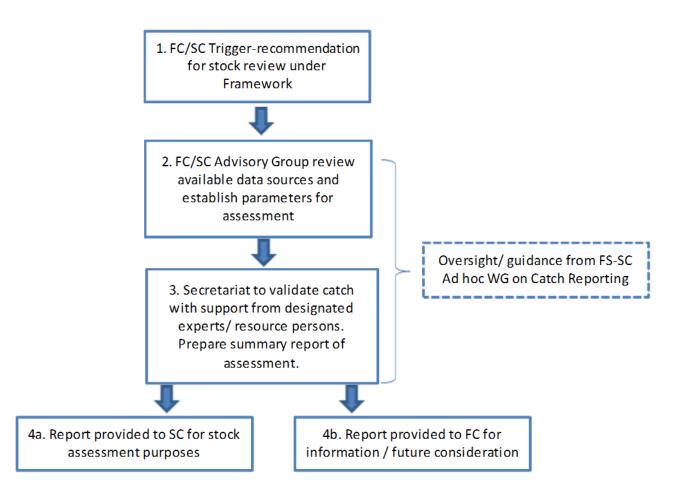

Regarding the VMS and CAT data, the Secretariat reported and the WG noted that this data source can be considered reliable due to the vessels' high level of compliance to the reporting requirement and to the quality of the reports received.

With regards to the haul-by-haul logbook information, the Secretariat reported that provision of the information to the Secretariat is a new requirement for fishing vessels in 2015. Compliance issues concerning timely submissions and compatibility of the report format with NAFO IT system were observed. The WG emphasized the importance of the format compatibility of the haul by haul reports and considered this as an urgent issue that needs to be resolved as soon as possible. The Secretariat informed the WG that it is working towards at IT solution with the aim of being able to read all report formats. Work should be completed by summer 2015.

Central to the development of the framework is the creation of Catch Data Advisory Group. The Terms of Reference (ToR) of the group is presented in Annex 3. The ToR specifies the composition of the group which comprises technical experts who are knowledgeable in the data sources and/or operational practices of the

NAFO fisheries, including STACTIC experts. Three stocks 2+3KLMNO Greenland halibut, 3M cod, and 3LMNO American plaice were initially considered as the priority stocks, noting the scheduled full assessment and development of the Management Strategy Evaluation for these stocks.

In the formulation of the ToR of the advisory group, the WG considered: data confidentiality, transparency, participation including roles and responsibilities of NAFO bodies, governance including reporting mechanism, and data requirements. The operation of the Catch Data Advisory Group is described in the flow chart below. The Catch Reporting WG would function as an overseer of the Catch Data Advisory Group, while trying to minimize overlaps and the proliferation of intersessional work for Contracting Parties.

6. Recommendations to forward to the Fisheries Commission and Scientific Council

It is **recommended**:

- 1) that the Ad hoc Working Group on Catch Reporting continues, with the same goals and objectives for at least another year;
- 2) that SC and FC give consideration to the establishment of the Catch Data Advisory Group and adopt its Terms of Reference (Annex 3); and
- 3) that SC and FC or an appropriate subsidiary body review the utility of data collection more generally, noting that some newer data sets provide more reliable and/ or timely information, making others redundant.

7. Other matters

There was no other matter discussed.

8. Adoption of the Report

This report was adopted through correspondence after the meeting.

9. Adjournment

The meeting was adjourned at 1200 hrs noon on Tuesday, 21 April 2015. The Chairs thanked the Secretariat for the support and the meeting participants for their cooperation and input. The participants likewise expressed their thanks and appreciation to the Chairs for their leadership.

PART B. REPORT OF THE NAFO JOINT FISHERIES COMMISSION-SCIENTIFIC COUNCIL WORKING GROUP ON RISK-BASED MANAGEMENT STRATEGIES (WG-RBMS), 22–24 APRIL 2015

Report of the Fisheries Commission and Scientific Council Working Group on Risk-Based Management Strategies (NAFO FC-SC Doc. 15/02)

9

22-24 April 2015

1. Opening

The Working Group co-Chairs Carsten Hvingel (Norway) and Kevin Anderson (Canada) opened the meeting at 1000 hrs on Wednesday, 22 April 2015 at the Prince George Hotel in Halifax, Nova Scotia, Canada. Representatives from Canada, Denmark (in respect of the Faroe Islands and Greenland), European Union, Norway, the Russian Federation and USA were in attendance (Part H, this volume). The Scientific Council was represented by its Chair, Don Stansbury (Canada). The Chairs welcomed participants and presented a short summary of the tasks to be addressed during this meeting.

10. Appointment of Rapporteur

The Fisheries Commission and Scientific Council Coordinators, Ricardo Federizon and Neil Campbell were appointed as co-Rapporteurs.

11. Adoption of Agenda

It was noted that the report of the 2014 WG-RBMS meeting stated that the group deferred giving further consideration to the development of a management strategy for the Div. 3LNO Northern shrimp (*Pandalus borealis*) stock until after the 2014 stock assessment was available, and requested this item be retained on the agenda for a future meeting. Consequently, this item was added to the provisional agenda, and the agenda (Part H, this volume) was adopted.

12. Review of Status of the WG Recommendations from the February 2014 Meeting

The recommendations contained in FC-SC Doc. 14/02 were presented at the joint sessions of Fisheries Commission and Scientific Council during the 2014 Annual Meeting, and were adopted by FC and SC. The Chair of Scientific Council presented the Scientific Council responses as related to the recommendations of this group.

It was noted that Scientific Council had extensive discussions on the recommendations of the working group, and agreed a list of points which were thought to be helpful to its work. The list is presented in Annex 3. It concerns references points, limits and targets in the Precautionary Approach framework.

Discussion on the implications of this advice for NAFOs precautionary approach framework was deferred to agenda item 5.

The Scientific Council Chair then presented progress on the definition of precautionary reference points for stocks assessed by Scientific Council. To date, B_{lim} has been defined for 12 stocks, B_{msy} for 8 and F_{lim} for 9. Definitions of reference points for Div. 3LNO Thorny skate, Div. 3NO White hake and Div. 2J + 3KL Witch flounder are expected in June (Annex 4, NAFO FC-SC Doc. 15/02).

The Chairs thanked Scientific Council for their work so far.

13. Discussions on the revision of the NAFO Precautionary Approach Framework

The Chairs presented a summary of the current implementation of the PA framework. It was noted that in some cases the guidelines for management and for making scientific advice, as spelled out in the NAFO PA framework, are ambiguous or do not match NAFO practice.

Discussion followed on whether it was desirable and/or feasible to align the PA framework and its implementation more closely; for this, it was suggested that convergence may have to happen from both sides: from the PA framework and from its implementation side. It was however recognized that the complexity of the technical aspects involved would be better handled by a smaller technical group (agenda item 9) and that FC should identify the scope for this work.

In the discussion of the Scientific Council response to WG-RBMS regarding reference points (agenda item 4) it was noted that the amended NAFO Convention (GC Doc. 08/03) in fact does not explicitly state that F_{msy} should be the limit reference point. In Article 3 subparagraph b it is stated that NAFO shall "*adopt measures*

based on the best scientific advice available to ensure that fishery resources are maintained at or restored to levels capable of producing maximum sustainable yield". In Article 3 subparagraph c it is stated that NAFO shall "apply the precautionary approach in accordance with Article 6 of the 1995 Agreement". The 1995 UN Fish Stocks Agreement is not precise when it comes to the technical discussion of reference points and therefore open to interpretation. Some international organizations (e.g. ICES) have not defined F_{msy} as a limit and still consider themselves well aligned with the principles of the precautionary approach. The Working Group considers the NAFO Convention sufficiently general not to complicate possible revisions to the NAFO PA framework as long as the 1995 Agreement is honored.

The Chairs thanked Scientific Council for their work in responding to the recommendations of the working group.

14. Discussions on the development of Div. 3NO witch flounder RBMS

At the 2014 Annual Meeting, the Fisheries Commission instructed the Working Group to undertake, at its meeting in 2015, the development of a risk-based management strategy for this stock (see FC Doc. 14/11 and FC Doc. 14/35). Further development of the assessment model for this stock is ongoing and will be presented to the Scientific Council in June. The Chairs thanked Scientific Council for their work on this topic. It was noted that the development of a management plan for this stock remains a priority and it is expected that more progress toward a management strategy for this stock would be possible after the June Scientific Council meeting.

15. Discussions on the finalization of Div. 3M cod RBMS

According to the workplan for the development of a harvest control rule (HCR) for Div. 3M cod, this Working Group was requested to offer feedback on the results of the work to date, before the 2015 June Scientific Council meeting (SCS Doc. 14/17 Revised, page 28).

The Div. 3M Cod management strategy evaluation (MSE) is described in another document (SCR Doc 14/44) based on the proposals of the Fisheries Commission and this Working Group reached in February 2014 (FC-SC Doc 14/02).

The management objectives set out for this harvest control rule are:

- 1. Very low risk of breaching B_{lim} . The probability of a spawning stock biomass under B_{lim} at 10% or lower.
- 2. Low risk of overfishing. For the model-free HCR only: The probability of F exceeding F_{msy} during the evaluation period should be kept at 30% or lower.
- 3. Low risk of steep decline. The probability of the decline of 25% or more of spawning stock biomass from year 0 to year 5 is kept at 10% or lower.
- 4. Maximum averages catch over the period. The average TAC over the period should be maximized.
- 5. Limited annual catch variation.

The general aim of the Div. 3M Cod MSE is to maintain the SSB in the safe zone as defined by the NAFO precautionary approach framework and to assure the optimum utilization, rational management and conservation of the Div. 3M cod stock. On this basis, the five performance objectives were tested via five different Performance Statistics. Six different operating models (OM) and two HCRs with three different F_{target} values were tested. A 20% constraint of annual variation of TAC was set. Based on this, a total of 24 scenarios were tested and results projected for the period 2014-2033.

Differences in the results come mainly from the assumed spawning stock recruitment relationship (SSR) and in a much lesser extent of assumed M (natural mortality) and the different F_{target} levels tested. The SSB have an increasing trend in all cases reaching a level well above B_{lim} at the end of the projected period (2033).

There are two main trends in yields, one for the scenarios with the model-based HCR and another for the scenarios with the model-free HCR. In the first case, landings decrease to 6 500 t in 2020, and after that increase until 2033 reaching values between 20 500 and 38 500 t, depending on the SRR assumed. In the case of the model-free HCR, catches decrease until 2020 and then remain between 6 000 and 9 000 t.

None of the tested HCR achieved all established performance objectives in the 2015-2023 period. Most performance targets were reached in the period 2024-2033.

11

The Working Group concluded that based on the analyses it could not recommend any of the HCRs tested for cod in Div. 3M. The failure to meet some of the management objectives in the 2015-2023 period is caused primarily by the high initial F and catch levels, in conjunction with the 20% stability constraint of maximum year-to-year changes in TACs. The Working Group noted in particular that it would not be possible to achieve simultaneously the stability requirement and the adopted level of risks (very low risk of breaching B_{lim} , low risk of steep decline). The Working Group also agreed that the level of risks adopted in the study arose from the PA framework and were open to interpretation It was noted that the element of risk interpretation, along with the starting point and the stability constraint could be examined further in the future work.

In addition some technical questions were brought to the table which the Working Group after some discussions proposed to defer to Scientific Council (agenda item 9).

Recognizing the scale of the work proposed here, and to ensure that the results of these analyses and alternative scenarios are examined, the Working Group requested that the Div. 3M cod RBMS be retained on the agenda for future meetings.

16. Development of a management strategy for Div. 3LNO Northern shrimp (Pandalus borealis)

At the 2014 WG-RBMS meeting, the group deferred giving further consideration to the development of a management strategy for the Div. 3LNO Northern shrimp (*Pandalus borealis*) stock until after the 2014 stock assessment was available, and requested this item be retained on the agenda for a future meeting. This assessment concluded that the stock was below B_{lim} , recruitment had been poor and recommended there be no directed fishery. The group recommended that the status of the stock continue to be monitored prior to further consideration of the development of a management strategy.

17. Recommendations to forward to the Fisheries Commission and Scientific Council

The Working Group **recommends that**:

- **1.** Scientific Council convenes a technical working group which could explore the revision of the precautionary approach.
- 2. Fisheries Commission identifies scope and priorities for such a review.
- **3.** Scientific Council gives a high priority to development of reference points for all stocks which lack them.
- 4. Scientific Council performs a review of the Div. 3M cod MSE.
- 5. Scientific Council discusses the following HCR options for Div. 3M cod:
 - a. Starting points
 - i. F_{status quo}
 - ii. 40% reduction
 - b. An HCR which meets management objectives 1 (very low risk of breaching B_{lim}) and 2 (low risk of overfishing) within five years, and within ten years, with:
 - i. risk calculated for each year in the time series
 - ii. risk calculated for the end of the periods (final year)
 - iii. risk averaged over the periods

The recommendations will be presented to Scientific Council and Fisheries Commission at the 2015 June Scientific Council and Annual Meeting for consideration and adoption.

18. Other matters

There were no other matters.

19. Adoption of the report

Having edited the recommendations in a plenary session, it was agreed that at the close of the meeting the substance of the last version of the report available in the SharePoint website would be considered final, that the report would be formatted thereafter by the rapporteurs, and that this would be circulated to participants for adoption via correspondence

20. Adjournment

The closing session of the meeting was called to order at 1400 hrs on 23 April 2015. The Chairs thanked participants for their positive approach to dialogue, the Secretariat for their support and the Rapporteurs for fulfilling their duties. The Chairs wished participants a safe journey home and the meeting was adjourned at 1435 hrs.

Participants of the 29 May–11 June Scientific Council Meeting

Left to right: Brian Healey- STACFIS Chair, Neil Campbell- SC Coordinator, Margaret Treble- STACPUB Chair, Katherine Sosebee- STACREC Chair, Don Stansbury- SC Chair, Angrew Cogswell- STACFEN Chair

REPORT OF SCIENTIFIC COUNCIL MEETING 29 May-11 June 2015

19

Chair: Don Stansbury

Rapporteur: Neil Campbell

I. PLENARY SESSIONS

The Scientific Council met at the Sobey Building, Saint Mary's University, Halifax, NS, Canada, during 29 May – 11 June 2015, to consider the various matters in its Agenda. Representatives attended from Canada, Denmark (Faroes and Greenland), the European Union (France, Germany, Portugal, Spain and the United Kingdom), Japan, Norway, the Russian Federation and the United States of America. Observers from WWF, Ecology Action Centre and Dalhousie University were also present. The Executive Secretary, Scientific Council Coordinator and other members of the Secretariat were in attendance.

The Executive Committee met prior to the opening session of the Council to discuss the provisional agenda and plan of work.

The Council was called to order at 1000 hours on 29 May 2015. The provisional agenda was **adopted** with modification. The Scientific Council Coordinator was appointed the rapporteur.

The Council was informed that the meeting was quorate and authorization had been received by the Executive Secretary for proxy votes from EU, Iceland, Japan, Norway, the Russian Federation and USA.

Scientific Council discussed the change in its working procedures introduced in 2014 whereby interim monitoring reports (IMRs) are drafted by the respective Designated Expert, and then subjected to a review process first by a 'Designated Reviewer', and finally, by the chair of STACFIS, and are examined in plenary only in situations where the interim monitoring update points to a potential re-opening of the full assessment. It was felt that this change had been beneficial to the work of the council, and this process would be used again.

The opening session was adjourned at 1000 hours on 29 May 2015. Several sessions were held throughout the course of the meeting to deal with specific items on the agenda. The Council considered **adopted** the STACFEN report on 9 June 2015, and the STACPUB, STACFIS and STACREC reports on 11 June 2015.

The concluding session was called to order at 1300 hours on 11 June 2015.

The Council considered and **adopted** the report the Scientific Council Report of this meeting of 29 May-11 June 2015. The Chair received approval to leave the report in draft form for about two weeks to allow for minor editing and proof-reading on the usual strict understanding there would be no substantive changes.

The meeting was adjourned at 1400 hours on 11 June 2015.

The Reports of the Standing Committees as adopted by the Council are appended as follows: Appendix I - Report of the Standing Committee on Fisheries Environment (STACFEN), Appendix II - Report of Standing Committee on Research Coordination (STACREC), and Appendix IV - Report of Standing Committee on Fisheries Science (STACFIS).

The Agenda, List of Research (SCR) and Summary (SCS) Documents, and List of Representatives, Advisers and Experts, are given in Appendix V-VII.

The Council's considerations on the Standing Committee Reports, and other matters addressed by the Council follow in Sections II-XV.

II. REVIEW OF SCIENTIFIC COUNCIL RECOMMENDATIONS IN 2014

There were no recommendations to Scientific Council in 2014.

Recommendations were received by Scientific Council from the FC-SC Working Groups on Catch Reporting (WG-CR) and on Risk-based Management Strategies (WG-RBMS). Due to the timing of these working groups, close to the SC meeting, the final draft of the RBMS report was not available for circulation, however it was agreed that the recommendations were finalised, and these were reviewed by the Council during this

meeting. These were addressed under Scientific Council Recommendations to General Council and Fisheries Commission (Section XIV).

20

III. FISHERIES ENVIRONMENT

The Council **adopted** the Report of the Standing Committee on Fisheries Environment (STACFEN), as presented by the Chair, Andrew Cogswell. The full report of STACFEN is in Appendix I.

The recommendations made by STACFEN for the work of the Scientific Council as **endorsed** by the Council, are as follows:

- a) STACFEN recommends consideration of support for one invited speaker to address emerging issues and concerns for the NAFO Convention Area during the 2015 STACFEN Meeting.
- **b) STACFEN recommends that** a sub-committee of STACFEN members be formed to discuss and draft a plan towards the reconfiguration and/or amalgamation of STACFEN and WGESA to be presented at the 2015 STACFEN Meeting.
- c) STACFEN recommends that a sub-committee of STACFEN members be formed to discuss the current state of Fisheries and Oceans Canada (DFO) Oceanographic Services (formerly ISDM and MEDS) data management responsibilities to NAFO and related mechanisms for the reporting of oceanographic data by member states and the subsequent means of accessing these data.

IV. PUBLICATIONS

The Council **adopted** the Report of the Standing Committee on Publication (STACPUB) as presented by the Chair, Margaret Treble. The full report of STACPUB is in Appendix II.

The recommendations made by STACPUB for the work of the Scientific Council as **endorsed** by the Council, are as follows:

- STACPUB **recommends** that the Secretariat contact WGESA for further instruction on the VME Guides in order to publish it for September 2015.
- STACPUB **recommends** that Scientific Council consider holding another symposium and that a list of potential topics and themes be put forward.
- STACPUB **recommends** that the NAFO Secretariat look into this matter, update their current list of SC members and create a forum for the electronic exchange of ideas that is accessible to SC members.

V. RESEARCH COORDINATION

The Council **adopted** the Report of the Standing Committee on Research Coordination (STACREC) as presented by the Chair, Katherine Sosebee. The full report of STACREC is in Appendix III.

The recommendations made by STACREC for the work of the Scientific Council as **endorsed** by the Council, are as follows:

- STACREC **recommends** that the NAFO Secretariat develop a framework for communicating tagging study information to vessels from Contracting Parties and Coastal States fishing in the Convention Area (e.g., via a link to this information on the NAFO website homepage).
- STACREC **recommends** that the Scientific Council support the EU H2020-BG02-2015 proposal "Predicting consequences of climate change on Aquatic FOOD production (AFOOD)" and agrees to serve on the external advisory board.

VI. FISHERIES SCIENCE

The Council **adopted** the Report of the Standing Committee on Fisheries Science (STACFIS) as presented by the Chair, Brian Healey. The full report of STACFIS is in Appendix IV.

There were no general recommendations arising from STACFIS. The Council endorsed recommendations specific to each stock and they are highlighted under the relevant stock considerations in the STACFIS report (Appendix IV).

VII. MANAGEMENT ADVICE AND RESPONSES TO SPECIAL REQUESTS

1. Fisheries Commission

The Fisheries Commission requests are given in Annex 1 of Appendix V.

The Scientific Council noted the Fisheries Commission requests for advice on Northern shrimp (Northern shrimp in Div. 3M and Divs. 3LNO (Item 1)) will be undertaken during the Scientific Council meeting on 9-16 September 2015.

a) Request for Advice on TACs and Other Management Measures

The Fisheries Commission at its meeting of September 2010 reviewed the assessment schedule of the Scientific Council and with the concurrence of the Coastal State agreed to request advice for certain stocks on either a two-year or three-year rotational basis. In recent years, thorough assessments of certain stocks have been undertaken outside of the assessment cycle either at the request of Fisheries Commission or by the Scientific Council given recent stock developments.

A.A.

Cod in Division 3M

Recommendation for 2016 and 2017

Scientific Council considers that yields at $F_{2012-14}$ are not sustainable over the longer term. In $F_{2012-14}$ projections there is a very high probability (>97%) of *F* exceeding F_{lim} .

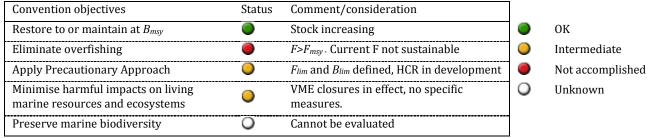

22

Yields at F_{lim} correspond to catches of 12 425 t in 2016 and 15 436 t in 2017. In keeping with the precautionary approach, Scientific Council recommends that the TAC be less than the catch corresponding to F_{lim}

Under both F_{lim} and $F_{2012-14}$ -based scenarios there is a very low probability (<1%) of SSB being below B_{lim} .

Management objectives

A management strategy evaluation for this stock is being developed by Fisheries Commission and Scientific Council, but has not yet been finalized. At this moment general convention objectives (NAFO/GC Doc. 08/3) are applied.

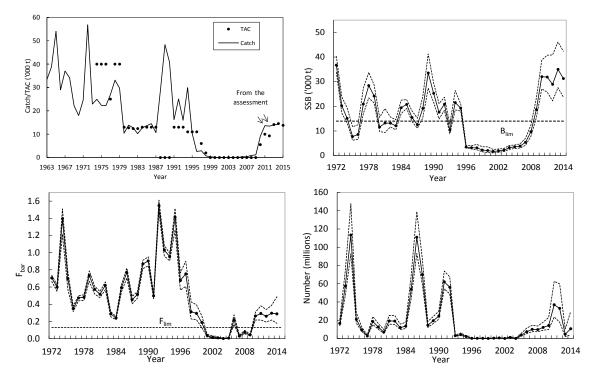

Management unit

The cod stock in Flemish Cap (NAFO Div. 3M) is considered to be a separate population.

Stock status

Current SSB is estimated to be well above B_{lim} . Recruitments since 2005 have been relatively high, especially in 2011 and 2012, although the 2013-2014 ones were much lower than the level observed in 2011-2012. *F* increased in 2010 with the opening of the fishery and it has remained stable since then at two times F_{lim} .

Reference points

 B_{lim} :

23

14 000 t of spawning biomass (Scientific Council 2008)

	Yield			$P(B_{year} < B_{lim})$				$P(F_{year} > F_{lim})$			$P(B_{2018} > B_{2014})$
	2015	2016	2017	2015	2016	2017	2018	2015	2016	2017	I (D2018 > D2014)
Flim	13 795	12 425	15 436	<1%	<1%	<1%	<1%	50%	50%	50%	95%
$\frac{3}{4}F_{lim}$	13 795	9578	12 486	<1%	<1%	<1%	<1%	<1%	<1%	<1%	97%
F2012-2014	13 795	23 435	23 435	<1%	<1%	<1%	<1%	>99%	>99%	>99%	79%
3⁄4 F ₂₀₁₂₋₂₀₁₄	13 795	18 637	20 469	<1%	<1%	<1%	<1%	97%	97%	97%	88%

Under all scenarios there is a very low probability (<1%) of SSB being below B_{lim} and for $F_{2012-2014}$ projections, a very high probability (>97%) of *F* exceeding F_{lim} .

Assessment

A quantitative model introduced in 2008 was used (Scientific Council 2008). Model settings were unchanged. The unavailability of independently verifiable catch estimates over 2011 – 2012 introduces an additional element of uncertainty in the assessment.

The next full assessment of this stock is planned for 2017.

Human impact

Mainly fishery related mortality. Other sources (e.g. pollution, shipping, oil-industry) are undocumented.

Biological and environmental interactions

Redfish, shrimp and smaller cod are important prey items for cod. Recent studies indicate strong trophic interactions between these species in the Flemish Cap.

Fishery

Cod is caught in a directed trawl fishery and as bycatch in the directed redfish fishery by trawlers. The fishery is regulated by quota.

	2006	2007	2008	2009	2010	2011	2012	2013	2014	2015
TAC	ndf	ndf	ndf	ndf	5.5	10.0	9.3	14.1	14.5	13.8
STATLANT 21	0.1	0.1	0.4	1.2	5.3	10.0	9.1	13.5	10.5	
STACFIS	0.3	0.3	0.9	1.2	9.2	13.6 ¹	13.4^{1}	14.0	14.3	

Recent catch estimates and TACs (000 t) are as follows:

¹ Estimated via the assessment model

Effects of the fishery on the ecosystem

No specific information available. General impacts of fishing gear on the ecosystem should be considered. A large area of Div. 3M has been closed to protect sponge, seapens and coral.

Special comments

A clear trend in the biological parameters of this stock in recent years has led to revisions in estimated numbers from one year's assessment to the actual ones in the next assessment. If this pattern continues, the projection results could be biased.

Commercial catches indicate a shift in the length distribution towards the minimum landing size, which could be a concern as it would result in a larger number of individuals being taken for the same TAC, and additionally, may result in increased discarding (see also VII.1.c.iii).

Sources of information

SCR Docs. 15/17, 15/33; SCS Docs. 15/04, 15/05, 15/06, 15/07, NAFO SC Reports 2014, 2008, NAFO/GC Doc. 08/3

Redfish in Division 3M

Advice June 2015

Recommendation for 2016 and 2017

Recent decline in proportion of *S* mentella and *S* fasciatus allows a marginal increase in TAC in 2016-17 to 7000t, without changing the exploitation rate on these species and having the stock remain at a relatively high level.

25

Management objectives

No explicit management plan or management objectives defined by Fisheries Commission. General convention objectives (NAFO/GC Doc. 08/3) are applied.

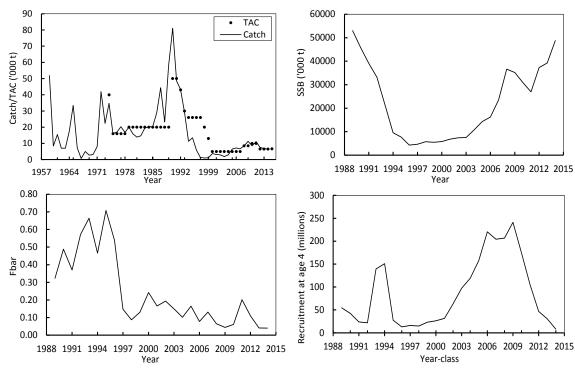

Convention objectives	Status	Comment/consideration		
Restore to or maintain at <i>B_{msy}</i>	0	<i>B_{msy}</i> unknown. Stock above historical average level	0	ОК
Eliminate overfishing	0	F_{msy} unknown, catch at low level over past 19 years	0	Intermediate
Apply Precautionary Approach	۲	Reference points not defined.	0	Not accomplished
Minimise harmful impacts on living marine resources and ecosystems	0	VME closures in effect, no specific measures, low bycatch reported.	0	Unknown
Preserve marine biodiversity	0	Cannot be evaluated		

Management unit

Catches of redfish in Div. 3M includes three species of the genus *Sebastes; S. mentella, S. marinus* and *S. fasciatus.* For management purposes they are considered as one stock (STACFIS 2015). Advice is based on data only for two species (*S. mentella & S. fasciatus*), labeled as Beaked redfish.

Stock status

The stock has increased since 1996 and has remained at a relatively high level in recent years. Fishing mortality has remained stable at low level since the late 1990s. Recruitment has declined in the past five years.

No updated information on biological reference points was available.

Assessment

Input data comes from EU Flemish Cap bottom trawl survey and the fishery (STACFIS 2015) and is considered good quality. A quantitative model (XSA) introduced in 2003 was used (STACFIS 2013). Model settings were in general kept unchanged from last assessment, with a natural mortality at 0.4 through 2006-2010, declining on 2011 and 2012 to 0.125. The magnitude of beaked redfish natural mortality (M) between 2013 and 2014 has been analysed on the sensitivity analysis of the present assessment, pointing out to a marginal increase of M to 0.14.

The next full assessment of this stock will be in 2017.

Projections

Given the uncertainty about the actual level of current natural mortality (see STACFIS, 2015) and its impact on short term model projections, Scientific Council decided not to use model predictions as a basis for the recommendation.

Human impact

Mainly fishery related mortality. Other sources (e.g. pollution, shipping, oil-industry) are undocumented.

Biology and Environmental Interactions

Since 2004 a rapid increase was observed on survey biomass both of golden (*Sebastes marinus*) and Acadian (*Sebastes fasciatus*) redfish stocks. Due to their shallower depth distributions these two redfish species overlap with cod to an extent greater than deep sea redfish (*Sebastes mentella*). Since 2006, the cod stock started to recover, while those two redfish stocks declined sharply. Redfish is an important component in the diet of cod, especially on those years when successful recruitment events were observed in redfish stocks.

Fishery

Redfish is caught primarily in bottom trawl fisheries, but some landings are reported from fisheries with midwater trawl. Cod is the main bycatch species in shallower waters, and Greenland halibut in deeper waters. In turn, redfish are also caught as bycatch in fisheries directed for cod and Greenland halibut. The fishery in NAFO Div. 3M is regulated by minimum mesh size and quota.

	2006	2007	2008	2009	2010	2011	2012	2013	2014	2015
TAC	5	5	5	8.5	10.0	10.0	6.5	6.5	6.5	6.7
STATLANT 21	6.3	5.6	7.9	8.7	8.5	9.7	6.7	6.8	6.5	
STACFIS	7.2	6.7	8.5	11.3	8.5	11.1	7.6	7.8	7.5	

Recent catch estimates and TACs (000 t) are as follows:

Effects of the fishery on the ecosystem

No specific information is available. General impacts of fishing gears on the ecosystem should be considered. A large area of Div. 3M has been closed to protect sponge, seapens and coral.

Special comments

Recent variability in levels of natural mortality undermine the general principle of using an *F* reference point for this stock.

In line with the precautionary approach, female spawning stock biomass should remain above the range of SSBs which generated the good year classes of the 2000's.

Sources of information: SCR Docs. 15/017, 028; SCS Docs. 15/04, 05, 06, 07

White Hake in Divisions 3NO

Advice June 2015

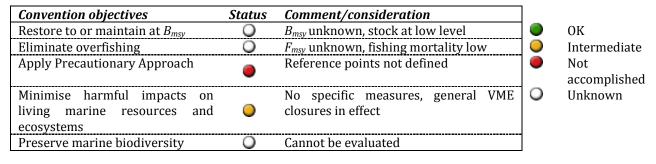

Recommendation for 2016-2017

Given the absence of strong recruitment, catches of white hake in Divs. 3NO should not exceed their current levels of 100-300 t.

27

Management objectives

No explicit management plan or management objectives defined by Fisheries Commission. General convention objectives (NAFO/GC Doc. 08/3) are applied. Advice is based on survey indices and catch trends in relation to estimates of recruitment.

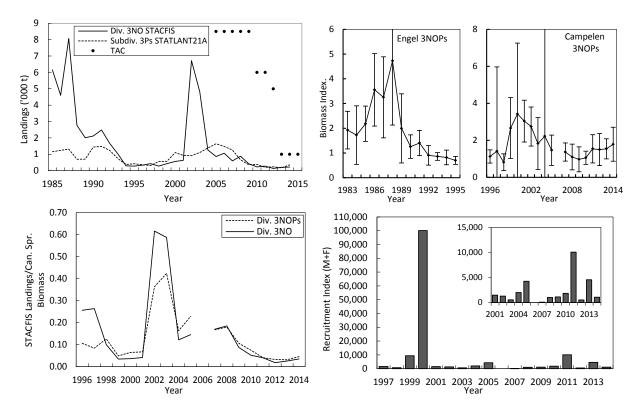

Management unit

The management unit is confined to Divs. 3NO, which is a portion of the stock that is distributed in Divs. 3NO and Subdiv. 3Ps.

Stock status

The stock biomass is at an average level. No large recruitments have been observed since 2000. Recruitment was higher in 2011, but not comparable to the very high recruitment observed in 2000. Fishing mortality is low.

Not defined. Attempts were made to define reference points in 2015 (STACFIS, 2015) but were not successful.

Assessment

Based upon a qualitative evaluation of stock biomass trends and recruitment indices. The assessment is considered data limited and as such associated with a relatively high uncertainty. Input data are research survey indices and fishery data (STACFIS 2015). The next full assessment of this stock will be in 2017.

Human impact

Mainly fishery related mortality has been documented. Mortality from other human sources (e.g. pollution, shipping, oil-industry) are undocumented.

Biology and Environmental interactions

On the Grand Bank, white hake are near the northern limit of their range, concentrating along the southwest slope of the Grand Bank at temperatures above 5°C. The major spawning area is located on the shelf-edge on the Grand Bank. Weaker ocean currents on the continental slope during the spawning period are hypothesized to reduce potential losses of eggs and larvae due to entrainment in the Labrador Current and increase recruitment potential.

White hake feed mostly on crustaceans and fish. Larger individuals are reported to be cannibalistic and to feed upon eggs and juveniles. In nearshore areas, white hake are also thought to predate on smaller juvenile cod. Predators of white hake include Atlantic cod, other fish species, Atlantic puffins, Arctic terns, other seabirds and seals.

Fishery

White hake is caught in directed gillnet, trawl and long-line fisheries. In directed white hake fisheries, Atlantic cod, black dogfish, monkfish and other species are landed as bycatch. In turn, white hake are also caught as bycatch in gillnet, trawl and long-line fisheries directing for other species. The fishery in NAFO Divs. 3NO is regulated by quota.

Advice June 2015

Cod in Divisions 3NO

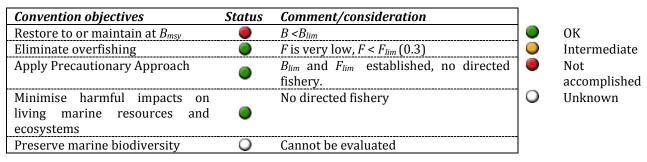

Recommendation for 2016 – 2018

No directed fishing on cod in 2016 to 2018 to allow for continued stock rebuilding. By-catches of cod in fisheries targeting other species should be kept at the lowest possible level. Projections based on either F_{SQ} or F=0 suggest a >99% probability that the stock will remain below B_{lim} by 2018.

29

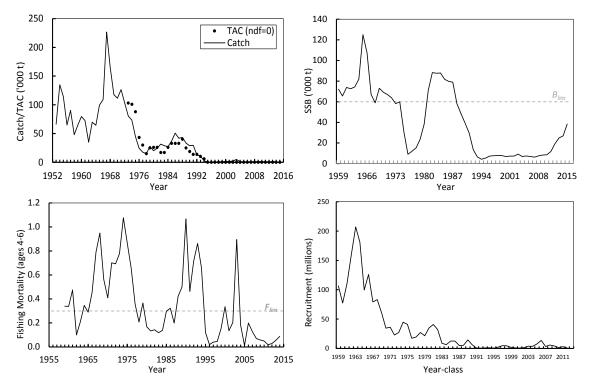

Management objectives

General convention objective are applied in conjunction with an Interim Conservation Plan and Rebuilding Strategy adopted in 2011 (NAFO/FC Doc. 11/22). The long-term objective of this plan is to achieve and to maintain the spawning stock biomass in the "safe zone" (PA framework, FC Doc. 04/18), and at or near B_{msy} .

Management unit

The stock occurs in Divs. 3NO, with fish occupying shallow parts of the bank, particularly the southeast shoal area (Div. 3N) in summer and on the slopes of the bank in winter.

Stock status

The spawning biomass has increased considerably over the past five years but the 2015 estimate of 38,454 t still represents only 64% of B_{lim} (60,000 t). This increase in biomass has been driven by the relatively strong 2005 and 2006 year classes and by fishing mortality values that are amongst the lowest in the time series

(F<0.1) and well below F_{lim} (0.3). More recent year classes do not appear as strong and hence despite the low fishing mortality, the increasing trend in SSB may not persist beyond the short term.

Reference	points
Merer ence	points

B _{lim} :	60 000 t of spawning biomass (SC, 1999)
F_{lim} (= F_{msy}):	0.3 (SC, 2011).

Projections

SSB is projected to remain below B_{lim} for both scenarios, increasing initially but then decreasing.

Fishing Mortality	Yield		$P(B_{year} < B_{year} < B_{yar} < B_{yar} < B_{yar} < B_{yar} < B_{yar} < B$	B _{lim})	$P(B_{2018} > B_{2015})$

F = 0	-	-	>99%	>99%	>99%	46%
F _{sq}	1348	1178	>99%	>99%	>99%	22%

Assessment

A sequential population analysis model was used, and the results were consistent with the previous assessment. Input data from 2011-2014 comes from research surveys and commercial removals (STACFIS 2015).

The next assessment is planned for 2018.

Human impact

Mainly bycatch related fishery mortality has been documented. Other sources (e.g. pollution, shipping, oil-industry) are undocumented.

Biology and Environmental interactions

Productivity of this stock was above average during the warm 1960s. During the cold 1990s, productivity was very low and surplus production was near zero.

Fishery

A moratorium was implemented in 1994. Catches since that time are by-catch in other fisheries.

Recent catch estimates and TACs are as follows:

	2006	2007	2008	2009	2010	2011	2012	2013	2014	2015
TAC	ndf									
STATLANT 21	0.3	0.7	0.7	0.6	0.8	0.8	0.7	1.1	0.7	
STACFIS	0.6	0.8	0.9	1.1	0.9	0.8	0.7	1.1	0.7	

ndf: No directed fishery

Effects of the fishery on the ecosystem

There is no directed fishery.

Special comments

As part of the Divs. 3NO Cod Conservation and Rebuilding Strategy "The Fisheries Commission shall request the Scientific Council to review in detail the limit reference point when the Spawning Stock Biomass has reached 30 000 t" (FC Doc. 15/01). As the stock has reached this level, SC notes that multiple stock-recruit points are required at SSB levels greater than 30,000 t prior to re-evaluation of this reference point as productivity at these levels of biomass is not well known.

Sources of information

SCR Docs. 15/7, 34; SCS Docs. 15-4, 5, 6, 7, 8, 9, 10

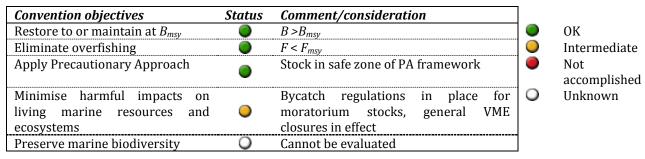

Recommendation for 2016 and 2017

Based on recent catch levels, fishing mortality up to 85% *Fmsy* corresponding to a catch of 26 300 t in 2016 and 23 600 t in 2017 has low risk (5%) of exceeding *Flim*, and is projected to maintain the stock well above *Bmsy*.

31

Management objectives

No explicit management plan or management objectives are defined by Fisheries Commission. General convention objectives (NAFO/GC Doc. 08/3) are applied. Advice is provided in the context of the Precautionary Approach Framework (NAFO/FC 04/18).

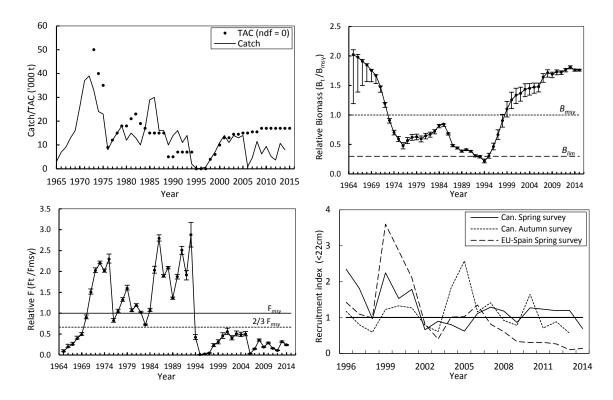

Management unit

The stock occurs in Divs. 3LNO, mainly concentrated on the southern Grand Bank and is recruited from the Southeast Shoal area nursery ground.

Stock status

The stock size has steadily increased since 1994 and is now well above B_{msy} . There is very low risk of the stock being below B_{msy} or F being above F_{msy} . Recent recruitment appears lower than average.

Blim 30% Bmsy

F_{lim} F_{msy} (STACFIS 2004 p 133).

Projections

Projections were conducted assuming two levels of catch in 2015: TAC level (17 000t) and the average of the 2007-2014 catch (7 400 t) followed by constant fishing mortality from 2016-2018 at 2/3 F_{msy} , 75% F_{msy} , and 85% F_{msy} . Although yields are projected to decline in the medium term at both levels of catch in 2015, at the end of the projection period, the risk of biomass being below B_{msy} is less than 1% in all cases. The probability of biomass increasing in the projection period (P(B_{2018} > B_{2014})) is <1%. The stock is well above B_{msy} and the projected levels of F result in catches higher than the estimated surplus production which will result in a decline in biomass toward B_{msy} .

Assessment

A surplus production model was used (STACFIS 2015). The results were consistent with the previous assessment and are considered to be reliable. Input data comes from research surveys and the fishery (STACFIS 2015) and is considered good quality. Next assessment: 2017.

Human impact

Mainly fishery related mortality has been documented. Other sources (e.g. pollution, shipping, oil-industry) are undocumented.

Biology and Environmental interactions

As stock size increased from the low level in the mid-90s, the stock expanded northward and continues to occupy this wider distribution. This expansion of the stock coincided with warmer temperatures; temperatures continue to warm, and will likely not limit the stock distribution in the near future.

Despite the increase in stock size observed since the mid-90s, the average length at which 50% of fish are mature has been lower for both males and females in the recent period. There also seems to have been a slight downward trend in weight at length since 1996. The cause of these changes is unknown.

Fishery

Yellowtail flounder is caught in a directed trawl fishery and as by-catch in other trawl fisheries. The fishery is regulated by quota and minimum size restrictions. Catches in recent years have been low due to industry-related factors. American plaice and cod are taken as by-catch in the yellowtail fishery. There is a 15% by-catch restriction on American plaice and a 4% limit on cod.

	2006	2007	2008	2009	2010	2011	2012	2013	2014	2015
TAC ¹	15.0	15.5	15.5	17	17	17	17	17	17	17
STATLANT 21	0.6	4.4	11.3	5.8	9.3	5.2	3.2	10.5	8.0	
STACFIS	0.9	4.6	11.4	6.2	9.4	5.2	3.1	10.7	8.0	

Recent catch estimates and TACs ('000 t) are as follows:

¹ SC recommended any TAC up to $85\% F_{msy}$ in 2009-2015.

Effects of the fishery on the ecosystem

Fishing intensity on yellowtail flounder has impacts on Divs. 3NO cod and Divs. 3LNO American plaice through by-catch. General impacts of fishing gears on the ecosystem should also be considered.

Special comments

Catch of yellowtail flounder has been below TAC in recent years. If catches increase, fishing mortality on Divs. 3NO cod and Divs. 3LNO American plaice will also increase.

Capelin in Divisions 3NO

Scientific Council deferred its advice on this stock to its September meeting to facilitate the involvement of the Designated Expert.

b) Monitoring of Stocks for which Multi-year Advice was Provided in 2014

The assessments (interim monitoring) found nothing to indicate a significant change in the status of the seven stocks for which multi-year advice was provided in 2014.

Accordingly, Scientific Council reiterates its previous advice as follows:

Recommendation for Redfish in Divs. 3LN (2014): For 2015 and 2016: Fishing mortality up to $1/3 F_{msy}$ corresponding to a catch of 10 200 t in 2015 and 2016 has low risk (<10%) of exceeding F_{lim} , and is projected to maintain the stock at or above B_{msy} . Fishing mortality up to $2/3 F_{msy}$ also has low risk of exceeding F_{lim} , and maintaining the stock at or above B_{msy} . However given the uncertainties in the assessment, a higher TAC should be reached by a stepwise increase from the current catch level..

Recommendation for Redfish in Div. 30 (2013): For 2014, 2015 and 2016: Catches have averaged about 13 000 t since the 1960s and over the long term, catches at this level appear to have been sustainable.

Recommendation for American plaice in Div. 3M (2014): For 2015, 2016 and 2017: There should be no directed fishery on American plaice in Div. 3M in 2015, 2016 and 2017. Bycatch should be kept at the lowest possible level

Recommendation for American plaice in Divs. 3LNO (2014): For 2015 and 2016: SSB remains below B_{lim} , therefore Scientific Council recommends that, in accordance with the rebuilding plan, there should be no directed fishing on American plaice in Divs. 3LNO in 2015 and 2016. Bycatches of American plaice should be kept to the lowest possible level and restricted to unavoidable bycatch in fisheries directing for other species.

Recommendation for Thorny skate in Divs. 3LNO (2014): For 2015 and 2016: The stock has shown little improvement at recent catch levels (approximately 5 000 t, over 2006 - 2013), therefore Scientific Council advises no increase in catches.

Recommendation for Witch flounder in Divs. 2J + 3KL (2013): For 2014, 2015 and 2016: No directed fishery to allow for stock rebuilding. By-catches of witch flounder in other fisheries should be kept at the lowest possible level.

Recommendation for Northern short-finned squid (*Illex***) in SA 3+4 (2013): For 2014, 2015 and 2016: During 2012, the northern stock component remained in a state of low productivity. Therefore, Scientific Council recommends a TAC of no more than 34 000 t/yr.**

c) Special Requests for Management Advice

i) Greenland Halibut TAC

The Fisheries Commission adopted in 2010 an MSE approach for Greenland halibut stock in Subarea 2 + Divs. 3KLMNO (FC Doc. 10/12). This approach considers a survey based harvest control rule (HCR) to set a TAC for this stock on an annual basis. The Fisheries Commission requests the Scientific Council to:

37

a) Monitor and update the survey slope and to compute the TAC according to HCR adopted by the Fisheries Commission according to Annex 1 of FC Doc. 10/12.

Scientific Council responded:

The TAC for 2016 derived from the HCR is 14 799 t.

As per the HCR adopted by the Fisheries Commission, survey slopes were computed using the most recent five years of survey data (2010-2014) and are illustrated below (Fig. 1). The data series included in the HCR computation are the Canadian Fall Divs. 2J3K index, the Canadian Spring Divs. 3LNO index and the EU Flemish Cap index covering depths from 0-1400m. Averaging the individual survey slopes yields *slope* = -0.0404. Therefore, the computed TAC is: 15 578*[1+2*(-0.0404)] = 14 391t. However, as this change exceeds 5%, the HCR constraint is activated and TAC2016 = 0.95*15578 = 14799t

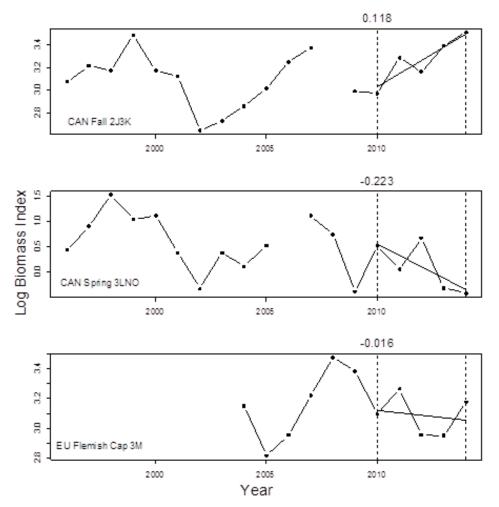

Fig. 1. Input for Greenland Halibut in Subarea 2 + Divs. 3KLMNO Harvest Control Rule. Slopes are estimated from linear regression of log-scale biomass indices (mean weight per tow) over 2010-2014. Survey data come from Canadian fall surveys in Divs. 2J3K.

ii) Greenland Halibut Exceptional Circumstances

a) Advise on whether or not an exceptional circumstance is occurring.

According to the indicator based on surveys, exceptional circumstances occurred in 2013 and 2014. One survey observation in each of 2013 and 2014 was below the 5th percentile of the simulated distributions, and one survey observation in 2014 was above the 95th percentile of the simulated distributions. Due to the unavailability of STACFIS catch estimates in 2011, 2012, 2013, and 2014, SC is unable to determine whether recent catches constitute an exceptional circumstance nor does it allow evaluation for some of the secondary indicators.

The fact that one of the surveys in 2014 is above the simulated distributions from one suite of operating models does not constitute a conservation concern. However, the fact that one of the surveys in 2013 and 2014 is below the simulated distributions of one suite of operating models is a conservation concern.

The "primary indicators" used to determine if exceptional circumstances are occurring are catch and surveys. The observed values are compared to the simulated distributions from both SCAA-based operating models and XSA-based operating models. If the observed values are outside of the 90% confidence interval (i.e. outside 5th-95th percentiles) from the simulations presented to WGMSE during September 2010, then SC shall advise FC that exceptional circumstances are occurring.

STACFIS catch estimates for 2011, 2012, 2013 and 2014 are not available. Therefore, SC cannot compare observed catches to the simulated distributions, and is unable to determine if exceptional circumstances are occurring in respect to this indicator. SC notes the management strategy for Greenland halibut assumed that the simulated catches would exactly equal the TACs generated from the HCR. The 90% confidence intervals for the simulated 2014 catches range from 14389 to 18606 t in the XSA based OMs and in SCAA based OMs, from 14731 to 16175 t. The STATLANT 21 catches for 2014 were 15 615 t, against a TAC of 15578 t.

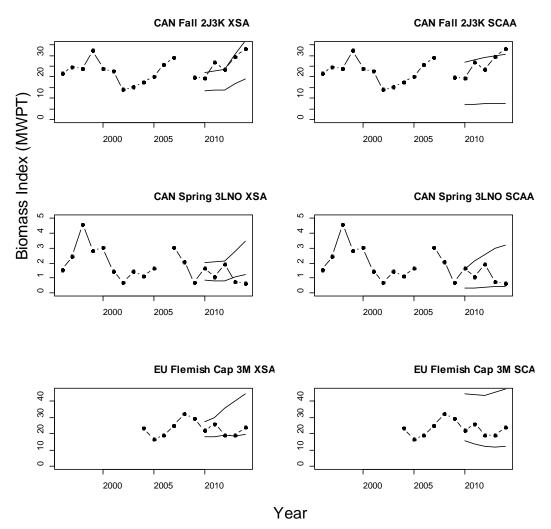

For the three surveys that comprise the input data to the HCR, the 2014 observed values were compared with composite distributions of simulated surveys for both SCAA-based and XSA-based operating models (Fig. 2). Out of the six comparisons possible in 2014 (three surveys; two sets of operating models), there was one case (Canadian fall survey 2J3K for the SCAA operating models) for which the observed survey index was above the 95th percentile. There was also one case (Canadian Spring 3LNO for the XSA operating models), for which the observed survey index was below the 5th percentile. This is the second consecutive year the observation for this index has been below the 5th percentile for the XSA operating models. The fact that one of the surveys in 2014 is above the simulated distributions from one suite of operating models does not constitute a conservation concern. However, the fact that one of the surveys in 2013 and 2014 is below the simulated distributions of one suite of operating models is a conservation concern.

When exceptional circumstances are occurring there are five secondary indicators which should be considered:

1. Data Gaps. There have been no data gaps in the survey series used in the HCR.

2. Biological Parameters: No new information is available.

3, 4 & 5. Recruitment, Fishing Mortality & Exploitable Biomass: Unable to update in relation to the 90% confidence intervals of the MSE as catches from 2011 – 2014 could not be estimated.

iii) Selectivity of cod and redfish in Div. 3M

The Fisheries Commission requests the Scientific Council to analyse and provide advice on management measures that could improve selectivity in the Div. 3M cod and Div. 3M redfish fisheries in the Flemish Cap in order to reduce possible by catches and discards.

The Scientific Council responded:

The implementation of sorting-grids in the Div. 3M cod fishery gear will reduce catch of small and immature individuals of cod. These devices would to a large extent prevent catches of individuals less than MLS (41 cm) and have the advantage also of reducing redfish by-catches and thereby reduce discards. It is estimated that by introducing sorting grids, the actual F_{msy} value and the equilibrium yield (catches) would increase but it should have a small impact in the equilibrium SSB. To quantify these improvements more precisely, selectivity experiments with the modified gears needs to be performed in the Flemish Cap area.

SC has reviewed some possible technical measures that could be applied in NAFO Div. 3M cod in order to reduce possible by-catches and discards based on studies carried out in the Barents Sea.

SC noted that in the Div. 3M cod fishery there has been decrease in the mean size of the catches observed in 2013 compared with previous years. The mode observed in the length distribution of catches in the 2013 fishery was very close to the Minimum Landing Size (MLS) approved for this species (41 cm) and it was quite different from 2012, when it was around 54 cm. In 2013, 32% of cod individuals caught were below the MLS while in 2012 it was only 10%.

40

SC reviewed the implementation of the 135 mm codend with 55 mm sorting-grid in the current gear that could be applied in NAFO 3M cod in order to reduce by-catch and discards based on studies carried out in the Barents Sea. Considering the selectivity parameters of the 135 mm codend mesh size and the Div. 3M cod biology, the mesh size used in the NAFO cod fishery (130 mm) is not the most appropriate as in its catches a large proportion of immature fish below MLS resulting in discarding. The L_{50} (length at which 50% of cod entering the net are retained) of the 135 mm codend with 55 mm sorting-grid was estimated to increase to around 55 cm. In addition to reducing the catch of small cod and with that discards, this alternative also has the advantage of reducing redfish by-catch. Sorting grids seem to have a greater survival rate of the selected fish than the diamond meshes and the exit windows.

The implementation of a selection pattern similar to the 135 mm codend with sorting grids would increase the actual F_{msy} value and the equilibrium catches but it should have a small impact in the equilibrium SSB. To quantify these improvements more precisely, selectivity experiments with the modified gears needs to be performed in the actual fishing area i.e. in the Flemish Cap area.

Other measures to avoid excessive catch of juveniles could be considered, e.g. the closure of the areas at less than 400 meters depth where these fish are more abundant. The effect in the exploitation pattern of this technical measure should be similar to the implementation of the 135 mm codend with sorting grids. However, this measure could increase the by-catch of redfish as this species is more abundant in depths more than 400 meters. Another problem of implementing these closures would be the effort concentration in small areas.

iv) Risk assessment for SAI on VME elements and species

The Fisheries Commission requests the Scientific Council to continue to develop work on Significant Adverse Impacts in support of the reassessment of NAFO bottom fishing activities required in 2016, specifically an assessment of the risk associated with bottom fishing activities on known and predicted VME species and elements in the NRA.

The Scientific Council responded:

The programme of work to deliver the assessment of bottom fishing activities by 2016 is progressing as intended. Recent developments have included the design of a template for the assessment report, the start of compilation of background ecological information, a description of the fisheries operating in the NRA, and further advances on the approach to be used for assessing the risk of Significant Adverse Impacts on VMEs.

The programme of work to deliver the assessment of bottom fishing activities by 2016 is progressing as intended. Recent developments have included a) the design of a template for the assessment report (see below), as well as guidelines for its content, b) the start of the compilation of background ecological information, and description of the fisheries operating in the NRA, and c) further advances on the approach to be used for assessing the risk of Significant Adverse Impacts on VMEs.

A template for the structure and content of the report to assess bottom fisheries has been defined (see NAFO Scientific Council Reports, 2014, 66 – 68; FC Doc. 15/01, Annex I.E), including which assessment task corresponds to which section of the report; e.g.:

Section 1: Introduction

Task No 2. "Existing baseline information on the ecosystems, habitats, and communities in the fishing area, against which future changes can be compared"

41

Approach to the section: This section is intended to be a summary of the environmental and general ecosystem background; detailed VME descriptions will be provided in Task 3. This section is envisioned as a brief introduction to the larger ecosystems where the VMEs are located. If pertinent, references to other more detailed sources can be made in this section, but the section itself should be kept short and to the point.

Template for the section:

1. NRA Footprint

a. General oceanographic processes: currents, water masses, temperature, salinity, bathymetry, etc for the entire region.

b. Ecosystem Production units: general description, productivity, biological oceanography.

- i. Grand Bank
- ii. Flemish Cap

c. Fish communities: Species, fish functional groups, community trends.

- i. Grand Bank
- ii. Flemish Cap

d. Benthic communities: ecoregions, habitats, species assemblages (VME and non-VMEs; the detailed VMEs description will be provided in a separate section).

- i. Grand Bank
- ii. Flemish Cap
- 2. NRA Seamounts.

Only general information. Refer to detailed VME section (Tasks 3 and 5) where seamounts are described as VME elements, unless some broader features are amenable and worthy of a general description.

Section 2: description of VME and VME elements

Tasks No 3 and 5. "Identification, description and mapping of VMEs, and VME elements"

Approach to the section: This section is intended to be a summary of all VMEs and VME elements in the NRA. It should provide a concise summary of the types, and locations of VMEs and VME elements identified in the NRA. Noting the caveats, this section is expected to heavily rely on the work already done for the evaluation of closures in 2014.

Template for the section:

1. NRA Footprint 2. NRA Seamounts

Section 3: Description of the Fisheries

Task No 1. "Description of fisheries"

Approach to the section: This section is intended to be a summary of all fisheries operating in the NRA, including their gear types, target species, areas of operation, etc.

Section 4: Impact analysis

Task No 4. "Analysis of likely impacts on VMEs"

Approach to the section: This section is expected to be focused on likely impacts on VMEs and, whenever possible, to discriminate likely impacts by fisheries. Depending on how the work develops, this section could be merged with Section 5.

Section 5: Risk Assessment

Task No 7. "Assessment of SAIs on VMEs"

Approach to the section: This section is intended to integrate the analysis of likely impacts (Section 4) in a framework compatible with standard risk assessment approaches that should allow identifying likely Significant Adverse Impacts (SAIs), as well as providing the basic blocks for potentially developing more comprehensive risk assessments if needed (e.g. when addressing Task 8). Depending on how the work develops, this section could be merged with Section 4.

SC highlights the usefulness of the fisheries report template (Section 3, assessment task 1) which provides summary data on gear type, target and by-catch species, fishing depths, and vessel capacity. In addition, fishery specific spatial effort maps are provided for 2013 and 2014 which will help to support the assessment of SAI in relation to functional considerations between VME habitat and commercial fisheries.

With respect to assessing SAI, a methodological framework to assess the interaction between fishing effort and VME biomass was presented, building upon the analysis performed and reported on last year. The area defined at risk of potential SAI is defined as the area of VME which lies outside the current fishery closures. Within the area of VME at *risk of SAI* the spatial distribution of VME indicator species biomass is observed to vary substantially. Therefore the level of risk of SAI within the VME (not closed to fishing activity) may also vary. To better understand the possible cause of the spatial variation in biomass within the VME area at risk a comparison of the VME indicator species biomass with the fishing effort was undertaken. This analysis revealed a significant relationship between VME species biomass and fishing effort for sponge VME, suggesting that parts of the VME may have experienced *past SAI*. However, the spatial pattern of biomass may also be responding to factors other than fishing effort, such as natural gradients in the habitat characteristics. Therefore to better understand the cause of the spatial pattern of VME indicator species biomass, and hence the estimation of *past SAI*, the inclusion of environmental data into the analysis needs to be considered.

The distinction between identifying areas of VME at *risk of SAI* and VME subject to possible *past SAI* is important, because an evaluation of the overall extent of VME impacted in the past, in relation to both VME assessed to be at risk and VME which is protected, is one of the key FAO SAI assessment criteria.

Accordingly, the assessment of SAI in the NRA focusses on the portions of the VMEs which lies outside of the current fishery closures, as defined by the review of VME closures in 2014 (SC 2014 Ref.). A scale of risk within the defined VME (outside of closed areas) has been determined by integrating the fishing effort data (VMS data from 2008 to 2012) with the observed VME indicator species biomass data (from survey trawls between 2000 and 2013) for each VME. This analysis has been undertaken for sponge, sea pen and large gorgonian VME, respectively, and estimates of the proportion of VME at *risk of SAI*, possible *past SAI* and VME protected has been determined. Preliminary results of this analysis are shown in Fig. 3.

At the present time, the kernel method is our best approach for determining the location and extent of VME (NAFO SC Report 2014, p.72 - 84). However, it would be expected that the depth contours, type of substrate, current and temperature fields will influence the fine scale boundaries of the mapped VMEs. Therefore to improve the precision of the present SAI analysis, through better resolution of the VME boundaries, consideration of the environmental characteristics should be attempted within the currently delineated VMEs.

In addition, it is noted that some parts of the VMEs (outside of closed areas) extend beyond the fishing footprint and therefore are not at direct risk of SAI through bottom fishing activities. The proportion of VME protected and at risk of SAI should be updated accordingly to take account of this situation.

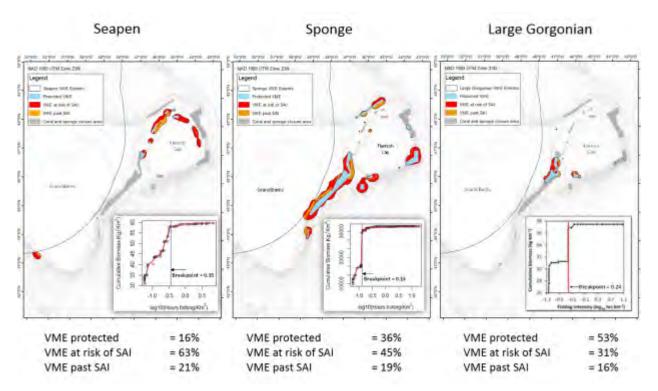

Fig. 3. Provisional SAI analysis showing the proportion of VME which is; i. protected, ii. at risk of potential SAI, and iii. possible past SAI; for seapen, sponge and large gorgonians. Areas of relatively low risk of SAI within with VME polygons are associated with areas of high fishing effort (shown in orange), by contrast areas at greater risk of SAI are associated with low or no fishing effort within the VME polygons (shown in red).

v) Impacts of removing candidate VME closures from survey design

The Fisheries Commission requests the Scientific Council investigate the impacts of removing the closed areas from the survey design for relevant stock surveys.

Scientific Council responded:

There was limited progress on this request from FC to investigate the impacts of removing the closed areas from the survey design for relevant stock surveys. A GIS analysis prepared by the Secretariat revealed that for Div. 3M, about 15% of the total stratified area overlaps with closed areas. Individual strata overlap ranged from 1% to 61%. Work is ongoing to quantify the overlap between VME protection areas and survey strata, as a first step in assessing the impact of excluding the closed areas from research survey design. Following this work, a comprehensive analysis of the time series of survey indices which include those strata overlapping closed areas will be required for various species.

SC reviewed a survey footprint prepared by the Secretariat using an equivalent method to that used to generate the fishery footprint (NAFO, 2009). The analysis also included an evaluation of closed VME area as a percentage of survey strata area and focused on Div. 3M. Overall $\sim 15\%$ of the combined strata area overlaps with closed areas and this ranges from 1% to 61% for individual strata. Closures in the Flemish Pass and on the northern slopes of the Flemish Cap coincide with the survey positions, while those on the eastern flank of the Cap appear to have been less affected. Work is ongoing to quantify the overlap between VME protection areas and survey strata, as a first step in assessing the impact of excluding the closed areas from research survey design.

It was also noted that for the EU Flemish Cap survey, there have already been some areas which are no longer included in the survey design, due to either high concentrations of sponge, or areas that are difficult to conduct successful trawling. There would be implications on statistical design if not all sampling units are

available to be selected with equal probability in the case of a stratified-random survey design, and hence the survey estimates would be biased. There may already be unmeasurable impacts introduced. It was also reported that Canada no longer conducts a survey in the deep water area of Divs. 3NO. This survey was only accomplished sporadically and has not been used to provide survey estimates for various deep water stocks.

SC considered that the next step to address this request will require a comprehensive analysis of the time series of survey indices which include those strata that overlap closed areas. This will include at a minimum, a regeneration of the time series of biomass and abundance estimates for various species, by age and/or length if available, and will require a significant amount of workload for those responsible for generating survey estimates.

vi) Comment on status and trends of cod in Divs. 2J + 3KL

The Fisheries Commission requests the Scientific Council is requested to comment on the trends in biomass and state of the stock in the most recent Science Advisory Report from the Canadian Science Advisory Secretariat.

Scientific Council responded:

Scientific Council endorsed the conclusions of the last update by Fisheries and Oceans Canada that the spawning biomass of cod in Divs. 2J + 3KL from the autumn DFO RV survey increased from 19% of the B_{lim} in 2011-13 to 26% in 2012-14, and although improving, remains in the critical zone of the DFO Precautionary Approach Framework.

The status of Divs. 2J+3KL cod was updated during a Fisheries and Oceans Canada Science Response process during March 2015 (DFO, 2015). This stock was last 'fully assessed' during March 2013, and a full assessment is planned for March 2016. The stock assessment update reviewed the main data sources for this assessment.

The conclusions from this update include:

- Indices from the autumn DFO RV survey and the Sentinel survey were generally higher in 2014, particularly in the north (Divs. 2J and 3K), indicating improvement in overall stock status (Fig. 4).
- Recent recruitment has improved, but is not expected to result in major changes to spawner biomass relative to B_{lim} in 2015.
- Tagging results indicated that exploitation levels continued to be low (\leq 5%) in 2014.
- The spawner biomass from the autumn DFO RV survey increased from 19% of B_{lim} in 2011-13 to 26% in 2012-14, and although improving, remains in the critical zone of the DFO Precautionary Approach Framework.

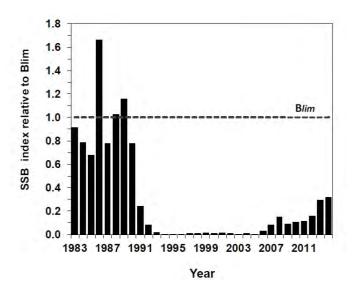

Fig. 4. SSB index from autumn DFO RV surveys in Divs. 2J3KL. The dashed line is the Limit Reference Point (B_{lim}) which is defined as the average SSB during the 1980s These conclusions were endorsed by Scientific Council.

vii) Full assessment of witch flounder in Divs. 3NO

The Fisheries Commission requests the Scientific Council to conduct a full assessment of witch flounder in Divs. 3NO.

Scientific Council responded:

<u>é</u>t

Witch Flounder in Divisions 3NO

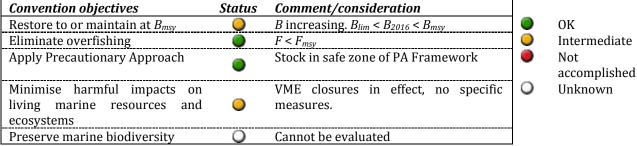

Advice June 2015

Recommendation for 2016 and 2017

Scientific Council noted that this is a newly reopened fishery. Acceptable risk levels have not yet been specified, but to allow the stock to continue to increase towards B_{msy} , exploitation in 2016 and 2017 should not exceed $\frac{2}{3} F_{msy}$, corresponding to catches of 2 172 t and 2 225 t respectively. Catches at this level will have a 3% risk of exceeding F_{lim} and <1% risk of driving the stock below B_{lim} .

Management objectives

The NAFO Fisheries Commission reintroduced a 1 000 t quota in 2015. Bycatches in commercial fisheries directed for other species should be kept to a minimum. General convention objectives (GC Doc. 08/3) are applied.

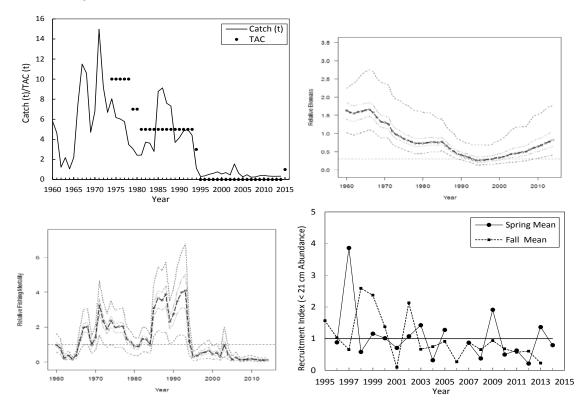

Management unit

The management unit is NAFO Divs. 3NO. The stock mainly occurs in Div. 3O along the southwestern slopes of the Grand Bank. In most years the distribution is concentrated toward this slope but in certain years, a higher percentage may be distributed in shallower water.

Stock status

The stock size has steadily increased since 1999 and is now at 81% B_{msy} . There is very low risk (<1%) of the stock being below B_{lim} or F being above F_{lim} . Recruitment (juveniles < 21 cm) since 2005 has generally been lower than average.

Reference points

Reference points were estimated from the surplus production model. Scientific Council considers that 30% B_{msy} is a suitable biomass limit reference point (B_{lim}) and F_{msy} a suitable fishing mortality limit reference point.

Projections and risk analyses

All projections assumed that the catch in 2015 was equal to the TAC of 1,000 t. The probability that $F > F_{lim}$ in 2015 was less than 1%. The probability of $F > F_{lim}$ increases to 26% at an F of 85% F_{MSY} . The population is projected to grow and the probability that the biomass in 2018 is greater than the biomass in 2014 is high under all scenarios. The population is projected to remain below B_{msy} for all levels of F examined with a probability of greater than 50%.

	Projections with catch in 2015 = 1	000 t

Yield (t) and risk of $F > F_{lim}$, $B < B_{lim}$ and $B < B_{msy}$ for projected F values of F_{2015} , 75% F_{2015} , 125% F_{2015} 2/3 F_{msy} 75% F_{msy} , and 85% F_{msy} .

Assessment

Previously this stock was assessed using trends in survey indices.

A surplus production model in a Bayesian framework was accepted as the basis for the assessment of this stock. The input data were catch from 1960 - 2014, Canadian spring survey series from 1984 - 1990, Canadian spring survey series from 1991 - 2014 (no 2006) and the Canadian autumn survey series from 1990 - 2013 (no 2014).

A maximum sustainable yield (*MSY*) of 3760 (2965 - 4820) tons can be produced by total stock biomass of 59 680 (44 600 - 73 700) tons (B_{msy}) at a fishing mortality rate (F_{msy}) of 0.06 (0.05 - 0.09). The relative population size (median B/B_{msy}) was below B_{lim} (30% B_{msy}) from 1993-1998. Biomass has since increased to a level of 81% B_{MSY} in 2014. The probability of being below B_{lim} in 2014 is very low.

Human impact

Mainly fishery related mortality. Other potential sources (e.g. pollution, shipping, and oil-industry) are undocumented.

Biological and environmental interactions

Witch flounder is distributed mainly along the southwestern slopes of the Grand Bank.

Fishery

NAFO reopened a directed fishery in 2015 with a TAC of 1 000 t. Prior to the repoening, witch flounder were previously caught via bottom trawl as bycatch mainly in otter trawl fisheries of skate and Greenland halibut.

	2006	2007	2008	2009	2010	2011	2012	2013	2014	2015
TAC ¹	ndf*	ndf	1.0							
STATLANT 21	0.2	0.2	0.2	0.3	0.4	0.4	0.3	0.3	0.3	
STACFIS	0.5	0.2	0.3	0.4	0.4	0.4	0.3	0.3	0.3	

Recent catch estimates and TACs are:

*ndf = no directed fishing

Effects of the fishery on the ecosystem

No specific information available. General impacts of bottom trawl gear on the ecosystem should be considered.

Special comments

No special comments.

viii) Assessment and advice for Splendid alfonsino (Beryx splendens)

The Fisheries Commission requests the Scientific Council to provide a stock assessment for Alfonsino, and recommendation.

Scientific Council responded:

Recommendation for 2016

Due to lack of abundance or exploitation data, no reliable stock assessment can be conducted.

To prevent extirpation of entire subpopulations of Alfonsino, fishing should not be allowed to expand above current levels on Kükenthal Peak (Div. 6G, part of the Corner Rise seamount chain) unless it can be demonstrated that such exploitation is sustainable, and fisheries on other seamounts should not be authorized.

In the absence of a stock assessment TAC recommendation is based on recent catch history (2009 – 2014). Scientific Council recommends exploitation should not exceed recent average levels of approximately 200 t or 16 days-on-ground on Kükenthal Peak, and no Alfonsino fishery on all other seamounts in the NRA. The sustainability of this level of removals is unknown.

Scientific Council also reiterates its advice provided in 2013 in the context of the Sargasso Sea and the protection of seamounts. (SC Report 2013, p310-315).

Management objectives

No management objectives defined by Fisheries Commission.

Management unit

Stock structure is unknown. Until more complete data on stock structure is obtained it is considered that separate populations live on each seamount.

Stock status

Unknown

Reference points

Not defined.

Assessment

No reliable assessment can be presented for this stock. The latest estimate of biomass is based on surveys dating back to 1995. Since then, only data on catches and effort are available. Due to lack of abundance or exploitation information, an analytical or survey based assessment was not possible.

Based on the ICES protocol for data-limited stocks (ICES, 2012) recent average catches during 2009-2014, either 200 t or 16 days on the fishing grounds (whichever is reached first), are recommended as the TAC for the 2016 Kukenthal Peak alfonsino fishery.

Period	Mean Catch (t)	Mean Effort
		(days on the Kukenthal Peak fishing grounds)
2012-2014	178	18
2009-2014	203	16
2005-2014	287	16

Human impact

Mainly fishery related mortality has been documented. Mortality from other human sources (e.g. pollution, shipping, oil-industry) are undocumented.

Alfonsino is distributed over a wide area which may be composed of several populations. Alfonsino is an oceanic demersal species which form distinct aggregations, at 300–950 m depth, on top of seamounts in the North Atlantic. Behavior and distribution of alfonsino are highly variable. Their pattern of diel vertical migration is associated with the vertical shift of its prey species which are located near the seabed during the daytime.

Population dynamics are uncertain with recent estimates suggesting high longevity (>50 years), while other estimates suggest a longevity of about15 years. Sexual maturation was found to begin in the second year of life at a mean length of 18 cm, and by age 5–6 years all specimens had become mature at 25–30 cm length.

On the Corner Rise Seamounts, Alfonsino were observed to spawn from May-June to August-September. Alfonsino were reported to feed on mesopelagic fish species (lanternfishes, hatchetfishes, viperfishes, etc.), squid and shrimp.

Fishery

The fishery currently takes place near the seabed with mid-water trawls in Div. 6G, on Kukenthal Peak, one of the two peaks on the Corner Seamount which is part of the Corner Rise Seamount chain (Fig. 5). Historically, catches of alfonsino in the NAFO regulatory area have been reported from Div. 6E-H from both midwater and bottom trawls.

The commercial aggregations of alfonsino on the Corner Rise Seamount chain (34-37°N, 47-53°W) have been found on three seamounts. Two of them, named "Perspektivnaya" (also known as "Kükenthal") and "Vybornaya", (also known as "MacGregor" or "C-3") are located in the NAFO Regulatory Area. Another seamount named "Rezervnaya" (also known as "Milne Edwards") is located in the Central Western Atlantic.

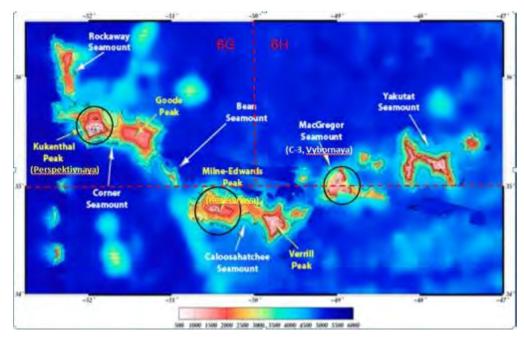

Fig. 5. Location of the Corner Rise Seamount complex in relation to NAFO Div. 6G-H (dashed lines).

The fishery started in 1976 with a catch of 10 200 t by Russian trawlers. Thereafter the number of vessels participating in the fishery ranged between 1 and 3, and catch ranged between 10 - 3500 t. There was no fishing from 1997 – 2003. A fishery was resumed by Spanish trawlers from 2005 – 2014, where catches have ranged between 54 - 1187 t, with no fishery in 2008 (Fig. 6).

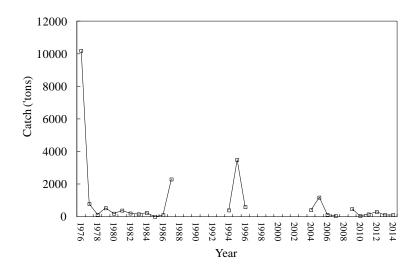

Fig. 6. Catches of Alfonsino from the Corner Rise Seamounts, 1976 - 2014.

On Kukenthal Peak, gear types used during the 2004 and 2012 exploratory fisheries included bottom and midwater trawls. The commercial fishery has operated since 2005 using a semi-pelagic trawl with the trawl gear, *"Pedreira"*.

Catch estimates and effort (no. vessels) from the Russian fishery, 1976 – 1987 are:

Year	1976	1977	1978	1979	1980	1981	1982	1983	1984	1985	1986	1987
Catch (t)	10200	800	130	530	200	390	210	160	240	10	110	2300
Effort (vessels)	3	2	1	2	1	2	2	3	1	1	1	3

Catch estimates and effort (no. vessels) from the Russian fishery, 1994 – 1996 are:

Year	1994	1995	1996
Catch (t)	400	3500	600
Effort (vessels)	1	2	2

Year	2004 ¹	2005	2006	2007	2008 ²	2009	2010	2011	2012	2013	2014
Catch (t)	415	1187	130	52	0	479	52	152	302	114	118
Effort (days on ground)	50	29	6		0	28	4	9	22	17	15
Effort (hours fished)	104	162	44	16	0	167	66	68	165	87	117
Effort (vessels)	1	3	1	1	0	1	1	1	1	1	2

Catch estimates and effort (hours fished, days on ground and no. vessels) from the Spanish fishery, 2004 - 2014 are:

Effects of the fishery on the ecosystem

Midwater trawls (pelagic and semi-pelagic) can produce significant adverse impacts (SAI) on VME communities, as per information provided by the Scientific Council in 2010 and further addressed in the Scientific Council 2015. Such impacts are typically associated with: 1.) habitat destruction or direct contact with VMEs by the gear when it is fished near the seafloor and 2.) lost gear that becomes entangled in VMEs. Given the slow growth/reproductive rates that characterize VME-forming species, these impacts to VMEs can cumulatively result in Significant Adverse Impact (SAIs).

Special comments

As a consequence of alfonsino spatial distribution associated with seamounts, their life-history, and their aggregation behavior, this species is easily overexploited and can only sustain low rates of exploitation.

Minority statement by Russia.

The Scientific Council noted difficulty in reaching consensus on the basis for provision of advice on alfonsino due to a dissenting view from Russia. The position of the Russian representative was that a TAC of 400 t for each of the three seamounts in the chain (for a total of 1200 t) would be more appropriate.

Sources of Information

SCS Docs. 13/21, 14/23; SCR Docs. 15/06 and 15/18; Vinnichenko, 1997, Russian Investigations and Deep Water Fishery on the Corner Rising Seamount in Subarea 6. NAFO Sci. Coun. Studies, 30: 41–49; ICES CM 2012/ACOM 68.

ix) The potential for acoustic surveys for Capelin

The Fisheries Commission requests the Scientific Council to liaise with the national institutes of the different CPs to see if – as recommended by STACFIS – acoustic surveys for capelin can be carried out.

The Scientific Council responded:

There are no plans for institutes of Contracting Parties to conduct acoustic surveys for capelin in Divs. 3NO.

The SC was not informed of any acoustic surveys planned for Divs. 3NO capelin. However, it was noted that acoustic data is being collected on Canadian spring and autumn surveys along the cruise track and during fishing sets, but the quality and value of this data is still being assessed. This data exists from the autumn surveys since 2008 and the spring surveys since 2012 and because it is collected along the survey track, and therefore not optimally designed for capelin distribution, it may only be useful to provide an estimate of availability of capelin to the bottom trawl rather than produce a reliable acoustic estimate of abundance.

¹From 2004 onward, fishing only refers to Kukenthal Peak. Prior to 2004, 50-70% of catch came from Kukenthal Peak and the remainder came from Milne-Edwards (outside NRA) and MacGregor Seamounts (Div. 6H). Catches in 2004 were taken in an experimental fishery.

²No fishing took place in 2008.

x) Depth distribution of Greenland halibut

There are some spatial and depth coverage deficiencies in the Greenland Halibut survey. It is suspected that there is a component of the Greenland Halibut stock of age-class 14+ that lives in depths under 1 500 meters and is therefore inaccessible to scientific trawling. The Fisheries Commission requests the Scientific Council to:

- a) comment on this hypothesis;
- b) indicate if information on this part of the stock would be useful for the stock assessment and the understanding of the stock dynamics;
- c) indicate if there are techniques available to assess the biomass below 1 500 meters, and;
- d) if useful and possible, implement such techniques in view of the next stock assessment.

Taken as a whole the surveys available for the assessment of Greenland halibut in SA2+Div 3KLMNO provide coverage of the majority of the spatial distribution of the stock and of the area from which the majority of catches are removed. Whilst studies using other techniques have encountered Greenland halibut at depths greater than the 1 500 m covered by the surveys currently used by the assessment, the majority of Greenland halibut encountered were at depths shallower than 1500 m. The otter trawl surveys mainly catch fish that are less than age 14. However, the main ages captured by the commercial fishery (5-10) are well sampled in the surveys. Any new index would need to be available for several years and its usefulness fully evaluated before it could be incorporated into the assessment of the stock, therefore would not be available in the short-term.

A single survey series covering the stock is not available. For assessment purposes multiple survey series are included in the evaluation of stock status. Most research vessel survey series providing information on the abundance of Greenland halibut are deficient in various ways and to varying degrees. However, taken as a whole the surveys available for the assessment of Greenland halibut in SA2+Divs.3KLMNO provide coverage of the majority of the spatial distribution of the stock and the area from which the majority of catches are removed. The spatial and depth coverage of surveys available for the assessment of Greenland halibut are given below:

Survey	Period	Divisions	Maximum Depth
EU-ESP 3NO	1997-2014	NRA 3NO	1460
EU-ESP & PRT FC survey	1988-2014	3M	730
	2004-2014	3M	1460
EU-ESP 3L	2003-2014	NRA 3L	1460
Canada (autumn)	1978-2014	2J3K	1500
Canada (spring)	1996-2014	3LNO	730

There have been studies in the area using bottom otter trawl to deeper depths (Snelgrove and Haedrich, 1985), using a remote operated vehicle (Baker *et al.* 2012) and a long line survey (Murua and DeCardenas, 2005). While all of these studies encountered Greenland halibut at depths greater than the 1500 m covered by the surveys currently used by the assessment, the majority of Greenland halibut encountered were at depths shallower than 1500 m. Both the mean length and the proportion of females increase with depth in Greenland halibut (Murua and DeCardenas, 2005).

The otter trawl surveys mainly catch fish that are less than age 14. However, the main ages captured by the commercial fishery (5-10) are well sampled in the surveys. This means that the assessment models should be able to provide reasonable estimates of the abundance of ages that are available to the otter trawl commercial fishery, and through the use of a plus-group, older fish. It should be noted that catches of Greenland halibut by otter trawl, longline and gillnet are different. These catches differ in terms of mean length and sex composition. The mean length of the otter trawl catch is lower and it has a smaller share of female fish than the catches of longlines and gillnets. This can be explained by the different selectivity of the gears (Pavlenko, 2005). In effect, otter trawl is around 80 times more efficient than longline in the catch of specimens with lengths of between 42 and 47 cm and longline is more efficient than trawl for specimens greater than 60 cm, being ten times more efficient for specimens greater than 80 cm (Jorgensen and Boje, MS 1992). Jorgensen (1995) concluded that the catchability of trawl, compared to longline, for Greenland halibut bigger than 50 cm decreases markedly.

More information on any portion of the stock could prove useful to the assessment. The main deficiency in data in recent years has been the unavailability of an accepted estimate of catch. Any new index would need to be available for several years and its usefulness fully evaluated before it could be incorporated into the assessment of the stock, therefore would not be available in the short-term.

xi) Review of impacts other than fishing in the NAFO Regulatory Area

The NAFO 2011 Performance Review Panel encouraged NAFO to consider whether activities other than fishing in the NAFO Convention Area may impact the stocks and fisheries for which NAFO is responsible as well as biodiversity in the NAFO Regulatory Area. Such activities might include oil exploration, shipping and recreational activities. Some work has been carried out as part of the ecosystem approach.

As the first step in the assessment of such impacts and for the implementation of the priorities of the Ecosystem Roadmap, could the Scientific Council provide a literature survey that would indicate what the risks are to the fish stocks and ecosystems in the NAFO Regulatory Area by looking at comparable situations.

The Scientific Council responded:

Scientific Council outlined the anthropogenic activities other than fishing that are occurring or have the potential of occurring in the NAFO Convention area and listed possible stressors and their possible impact on fish stocks and the ecosystem.

A summary of the factors considered by Scientific Council as potential stressors to the fish stocks and ecosystems of the NAFO regulatory area is given in Table 1. A full literature review can be found in the WG-ESA Report (SCS Doc. 14-23).

Table 1.Factors considered by Scientific Council as potential stressors to the fish stocks and
ecosystems of the NAFO regulatory area (see SCS Doc. 14-23).

Anthropogenic activity	Stressor	Potential effects	Potential Risk to			
			Fish Stock /Fisheries	Ecosystem		
Fishing	Not Applicable to this review					
Transportation	Ballast Water Exchange	Risk of introduction of pelagic organisms/larvae with alternative ballast water exchange zones in NAFO area	Fish Health and competition from aquatic invasive species (AIS).	Mostly studied for coastal zones

xii) Impacts of mid-water trawls on VME indicator species

The Fisheries Commission requests the Scientific Council to evaluate the impact of mid-water trawls on VME indicator species in those instances when the gear makes contact with or is lost on the bottom.

59

The Scientific Council responded:

Midwater trawls (pelagic and semi-pelagic) can produce significant adverse impacts (SAI) on VME communities, as per information provided by the Scientific Council in 2010 and further addressed here. Such impacts are typically associated with: 1.) habitat destruction or direct contact with VMEs by the gear when it is fished near the seafloor and 2.) lost gear that becomes entangled in VMEs. Given the slow growth/reproductive rates that characterize VME-forming species, these impacts to VMEs can cumulatively result in Significant Adverse Impact (SAIs).

The definition of a midwater trawl is not described in the CEM except for Article 13 2 (f), the description for redfish midwater trawls. 'Bottom fishing activities' are described in Article 1 of the CEM as "bottom fishing activities where the fishing gear is likely to contact the seafloor during the normal course of fishing operations". Fishermen are able to deploy midwater trawls anywhere in the water column and studies have shown that midwater trawl fishing meets this definition. Inadvertent bottom contact can occur when fishing with midwater trawls on seamounts due to strong gyres associated with the topography of these geologic features and as a result of fishing midwater trawls close to the bottom.

Scientific Council recommends that, midwater trawl fisheries on seamounts record all VME indicator bycatch, regardless of the amount caught.

Midwater trawls are typically used to fish in the upper water column to catch schooling fish such as sardines, anchovies, herring, hake and mackerel. However, in some fisheries midwater trawls are deployed near the seafloor where the behavior of the target species offers increased CPUE. For example, southern blue whiting (Micromesistius australis), orange roughy (Hoplostethus atlanticus) and alfonsino (Beryx spp.) are all fished within meters of the seafloor and may also be fished with bottom trawls. Unequivocal evidence of bottom contact with midwater trawls by New Zealand vessels fishing alfonsino in the South Pacific Regional Fisheries Management Organisation (SPRFMO) Convention Area was documented for 10% on average (range 6-12%) of 238 midwater trawl tows during each of three years (2011–2013) and an average of 16% (range 13-19%) of midwater trawl tow had strong evidence for having had bottom contact (Tingley, 2014). In certain areas, the incidence of strong evidence for bottom contact was as high as 25% due to local bottom topography interacting with midwater trawl gear. These results are higher than expected and may be due to the development of stronger nets that can be deployed both on the bottom and in midwater without gear loss (e.g., Vónin Super Height³), because no gear was lost in the New Zealand study, although the net was torn in a few cases (Tingley 2014). These results led the SPRFMO Scientific Council (SC) to conclude that "mid-water trawling for bentho-pelagic species (e.g., alfonsino) falls under the description of 'bottom fishing' as defined in paragraph 4 of CMM 2.03". The SPRFMO SC also recommended that the Commission modify their CMM (Conservation and Management Measure) 2.03 to "take into account the relative impact on VMEs of different fishing methods and practices, and to specifically address midwater trawling for bentho-pelagic species" (SPRFMO 2014).

Interaction between midwater trawls and VMEs on seamounts is expected to be higher because on seamounts the gear is more likely to inadvertently contact the bottom. Midwater trawls are difficult to control and often fish erratically in the deep waters overlying seamounts and their steep slopes because such areas are known to have strong, complex gyres and current patterns as a result of their protruding geological features. Consequently, direct contact between the midwater trawls and the sessile VME communities inhabiting seamounts is generally unavoidable (Clark *et al.* 2006). This is consistent with Murillo *et al.* (2008) who reported that 6.5% of midwater trawl hauls conducted during Exploratory Fishing on the Corner Rise Seamounts contained coral bycatch. On the New England Seamount complex only 3 hauls were conducted but all contained coral bycatch. While these figures are high, they may represent only a portion of the total number of hauls which contacted the bottom because only hauls with coral bycatch were reported. In New

³ http://www.vonin.com/en/fishing/semi-pelagic-trawls/vonin-super-height-semi-pelagic-trawls

Zealand, strict regulations exist to monitor and control the use of midwater trawls on seamounts in order to avoid any bottom contact and consequent impacts on VMEs. To ensure that there is little risk of midwater trawls touching the bottom, a buffer zone of 100 m from the seafloor has been set has been set for midwater trawl fishing and this is enforced through mandatory submittal of vessel data collected from electronic net monitoring sensors that record the height of the footrope above the seabed during at least every 15 seconds⁴.

60

Since 2005, an alfonsino fishery using midwater and bottom trawls has been conducted by Spain on the Corner Rise seamounts. Catches for this fishery ranged from about 50 to 1 200 t and effort ranged from 4 days to 50 days. There is no information on the degree of bottom contact during this fishery. No notifications of encounters above thresholds (currently 7kg of seapen, 60kg corals and 300kg sponges, per set) have been received by the NAFO Secretariat [for any fishery] since the measures were introduced in 2007.

With respect to the impacts of lost fishing gear on VME indicator species, midwater trawl gear can become snagged on the bottom or deposited on the bottom if burdened with catch which weighs it down after it is lost, in which case it may cause damage to the benthos, including VMEs (Donaldson *et al.* 2010).

21. Coastal States

a) Request by Denmark (on behalf of Greenland) for Advice on Management in 2015-2017

i) Roundnose grenadier in SA 0+1

For Roundnose grenadier in Subarea 0 + 1 advice was in 2014 given for 2015-2017. Denmark (on behalf of Greenland) requests the Scientific Council to continue to monitor the status of Roundnose grenadier in Subareas 0 and 1 annually, and should significant changes in the stock status be observed (e.g. from surveys) the Scientific Council is requested to provide updated advice as appropriate.

Scientific Council responded:

The assessments (interim monitoring) found nothing to indicate a significant change in the status of these stocks. Accordingly, Scientific Council therefore did not change the advice. The next full assessment of this stock will take place in 2017.

ii) Golden redfish, Demersal Deep-sea redfish, Atlantic wolfish, Spotted wolfish and American plaice in Subarea 1

Advice for golden redfish (Sebastes marinus), demersal deep-sea redfish (Sebastes mentella) American plaice (Hippoglossoides platessoides), Atlantic wolffish (Anarhichas lupus) and spotted wolffish (A. minor) in Subarea 1 was in 2014 given for 2015-2017. Denmark (on behalf of Greenland) requests the Scientific Council to continue to monitor the status of these species annually, and should significant changes in stock status be observed the Scientific Council is requested to provide updated advice as appropriate.

Scientific Council responded:

The assessments (interim monitoring) found nothing to indicate a significant change in the status of these stocks. Accordingly, Scientific Council therefore did not change the advice. The next full assessment of this stock will take place in 2017.

iii) Greenland halibut in Div. 1A (inshore)

Advice for Greenland halibut in Div. 1A (inshore) was in 2014 given for 2015-2016. Denmark (on behalf of Greenland) requests the Scientific Council to continue to monitor the status of Greenland halibut in Div. 1A (inshore) annually, and should significant changes in stock status be observed, the Scientific Council is requested to provide updated advice as appropriate.

⁴ http://www.fish.govt.nz/en-nz/Environmental/Seabed+Protection+and+Research/Benthic+Protection+Areas.htm

Scientific Council responded:

The assessments (interim monitoring) found nothing to indicate a significant change in the status of these stocks. Accordingly, Scientific Council therefore did not change the advice. The next full assessment of this stock will take place in 2016.

61

iv) Pandalus borealis east of Greenland and in the Denmark Strait (in conjunction with ICES)

Furthermore, the Scientific Council is in cooperation with ICES requested to provide advice on the scientific basis for management of Northern shrimp (Pandalus borealis) in Denmark Strait and adjacent waters east of southern Greenland in 2016 and for as many years ahead as data allows for.

The Scientific Council deferred responding to this request to the September SC/NIPAG meeting.

b) Request by Canada and Denmark (Greenland) for Advice on Management in 2016

i) Greenland halibut in Div. 0A and the offshore areas of Div. 1A, plus Div. 1B

The Scientific Council is requested, subject to the concurrence of Denmark (on behalf of Greenland) as regards Subarea 1, to provide an overall assessment of status and trends in the total stock area throughout its range and to specifically advise on TAC levels for 2016, separately, for Greenland halibut in Divs. 0A+1A (offshore) and 1B, and Divs. 0B+1C-F. The Scientific Council is also asked to provide advice on any other management measures it deems appropriate to ensure the sustainability of these resources.

The Scientific Council responded:

Greenland halibut in SA 0 + Div. 1A Offshore and Divs. 1B-1F

Recommendation for 2016

Divs. 0A+1AB: Scientific Council advises that there is a low risk of Greenland halibut in Div. 0A and Divs. 1AB being below B_{lim} if the TAC for 2016 remains unchanged and catches should not exceed 16 000 t.

62

Divs. 0B+1C-F: Scientific Council advises that there is a low risk of Greenland halibut in Divs. 0B and Div. 1C-F being below B_{lim} if the TAC for 2016 remains unchanged and catches should not exceed 14 000 t.

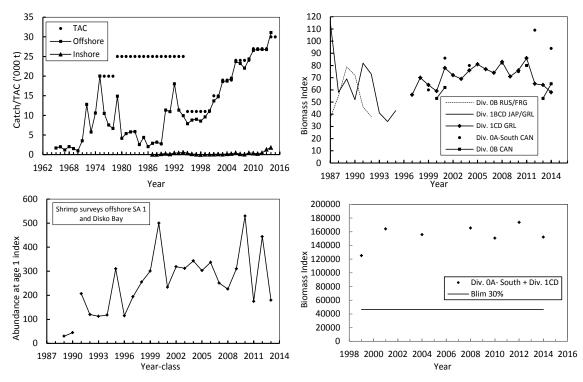

Management objectives

Canada requested Scientific Council to provide advice on this stock within the context of the NAFO Precautionary Approach Framework (SCS Doc. 15/02).

Management unit

The Greenland halibut stock in Subarea 0 + Div. 1A offshore and Divs. 1B-1F is part of a population distributed in Davis Strait and southward to Subarea 3, however, two separate assessments are made on this population. Since 2002 advice for the Subarea 0 +Div. 1A offshore and Divs. 1B-1F stock has been given separately for the northern area (Div. 0A and Divs. 1AB) and the southern area (Divs. 0B and 1C-F).

Stock status

The biomass (combined Div. 0A + Divs. 1CD index) is stable and was well above B_{lim} in 2014. Two of the four most recent recruitments have been above average. Most standardized CPUE indices have been increasing in recent years.

Divs. 0B+1C-F: The biomass index in Div. 0B increased between 2013 and 2014 and is at about average for the short time period. The biomass index for Divs. 1CD has been decreasing since 2011 and was in 2014 at the lowest level seen since 1997. Length compositions in the catches and deep sea surveys have been stable in

recent years. Standardized CPUE has decreased between 2009 and 2012 but increased again in 2013 and 2014. The Standardized CPUE for gillnets in Div. 0B has been increasing since 2007 and in 2014 was at the highest level in the time series.

Divs. 0A+1AB: The biomass index decreased slightly between 2012 and 2014 but is still at a high level. Length composition in the 0A-South survey shows minor modes at 18 cm in 2012 and 33 cm in 2014 that may reflect the high abundance of 2011 and 2013 year classes. Length frequencies were not available for the SA0 fishery in 2013 and 2014. Combined Standardized CPUE indices for Div. 0A and 1AB have been increasing since 2006.

Reference points

Age-based or production models were not available for estimation of precautionary reference points. In 2014 a preliminary proxy for B_{lim} was set as 30% of the mean biomass index estimated for surveys conducted between 1997 and 2012 in Divs. 1CD combined with surveys from 1999-2012 in Div. 0A-South to establish a proxy for B_{lim} for the entire stock.

Assessment

Based upon a qualitative evaluation of stock biomass trends compared to the limit reference point, and recruitment indices. The assessment is considered data limited and as such associated with a relatively high uncertainty. Input data are research survey indices and fishery data (STACFIS 2015). The next full assessment of this stock will be in 2016.

Human impact

Mainly fishery related mortality has been documented. Other sources (e.g. pollution, shipping, oil-industry) are undocumented.

Biology and Environmental interactions

A study showed that year class strength and abundance of Greenland halibut at West Greenland may be driven by environmental pulses.

Fishery

Catches have increased in response to increases in the TAC from approximately 10 000 t in the late 1990s to approximately 27 000 t during 2010 to 2012 then increased to 31 100 t in 2014. The TAC is 30 000 t in 2015.

	2006	2007	2008	2009	2010	2011	2012	2013	2014	2015
TAC	24	24	24	24	27	27	27	27	30	30
SA 0	12	11	11	12	13	13	13	13	15	
SA 1 exl. Div. 1A inshore	12	12	12	12	14	14	14	15	16	
Total STATLANT 21 ¹	242	22 ²	22	25	27	27	27	28	31	
Total STACFIS	24	23	23	25	27	27	27	28	31	

Recent catch estimates and TACs are as follows:

¹ Excluding inshore catches in Div. 1A

² Excluding 2 000 – 4 300 t reported by error from Div. 1D

Effects of the fishery on the ecosystem

A study has shown that the fishery in Divs. 1CD has not affected the abundance of the nine most common bycatch species but a decrease in mean weight is observed for a number of the species. General impacts of fishing gears on the ecosystem should also be considered.

Special comments

A quantitative assessment of risk at various catch options is not possible for this stock. Therefore it is not possible to quantitatively evaluate whether the TAC is sustainable.

Sources of information

SCR Docs. 15/03, 16, 24, 25, 30, 32, 35; SCS Docs. 15/07, 08, 10;

Subject to the concurrence of Canada as regards Subarea 0 and 1, Denmark (on behalf of Greenland) further requests the Scientific Council before December 2015 to provide advice on the scientific basis for management of Northern shrimp (Pandalus borealis) in Subarea 0 and 1 in 2015 and for as many years ahead as data allows for.

64

Scientific Council deferred this advice to the September Scientific Council/NIPAG meeting.

c) Request by Canada for Advice on Management

i) Requirements for risk-based advice on Greenland halibut in Divs. 0A, 1A (offshore) and 1B

Recognizing that this is a data poor fishery, and that no model exists at this time to provide risk-based advice to inform management options, the Scientific Council is also asked to identify what would be required in order to provide risk based advice in the future.

Scientific Council responded:

A quantitative assessment of risk at various catch options is not possible for this stock. Until there is a successful quantitative model fit to the stock trends it will not be possible to provide risk based advice for this stock. Both age-structured and biomass models have been explored for the assessment of this stock. Research on age determination continues but is not expected to be resolved in the near future so it is not possible to apply age-based models (e.g. XSA) to the stock at this time. There is little variation in the biomass and abundance indices and the time series is short which are likely the main factors limiting previous attempts to apply production models (e.g. ASPIC and Schaefer).

ii) Harvest control rules for Harp seals

Canada requests the Scientific Council to explore the impact of proposed harvest strategies that would maintain the North Atlantic harp seal population at a precautionary level of a PA framework, using the Canadian levels as a case study, and that would have a low risk of decreasing below the critical level.

Scientific Council endorsed the findings of the working group, and noted that this is ongoing work:

A MSE provides an approach for addressing both policy and process conflicts in harvest co-management. It is explicitly designed to identify to examine ongoing or potential harvest strategies that are robust to uncertainty and natural variation, and that balance biological and socio-economic objectives. The management strategy evaluation process involves defining a set of operational objectives, identification of candidate management procedures (i.e. data collection, stock assessment, and harvest control rules), and evaluates the performance procedures of the procedures against the objectives. In contrast to the earlier traditional approach to management, it does not necessarily identify an optimal strategy or decision. Instead it seeks to explicitly identify some of the trade-offs that may be necessary to achieve different management objectives; fisheries data and stock assessment models; harvest control rule(s), a simulation framework that allows testing of the different management objectives taking into account different levels of uncertainty; and a means of calculating and presenting how the management objectives performed during the simulations, expressed in terms of conservation, socio-economic or other criteria (performance indicators).

The request received by the working group was to:

1) Identify the catches necessary to reduce the population to 5.4M animals assuming:

- i) Catches consisting of 90% YOY and 50% YOY
- ii) Over periods of 5, 10, and 15 years

2) Identify the catches necessary to reduce the population to 6.8M assuming:

- iii) Catches consisting of 90% YOY and 50% YOY
- iv) Over periods of 5, 10, and 15 years

3) What would be the sustainable future catches possible with a reduced population and assuming there is a 95% probability of remaining above the Limit Reference Point (defined as the current N30).

The WG discussed how these scenarios might be examined within a MSE environment. Since there are two models currently being used in the assessments of harp seals, one in the NE Atlantic and another for the NW Atlantic population it was suggested that initially, the behaviour of the NE Atlantic model would be examined using the NW Atlantic assessment data to see how the model behaved when annual reproductive rate data were available. At the same time, the NW Atlantic model would examine the impacts of the different catch options on the population. Additional considerations included: updating the projections every 5 years, by assuming a new survey was flown to estimate pup production; assuming two different future trends in reproductive rates. One set of projections would assume that reproductive rates varied in a density-dependent manner, while a second series would assume that future reproductive rates would vary in a manner that has been observed over the last 5 years.

The model comparisons and projections will be carried out over the coming year, and reviewed by correspondence. Further work on a MSE will be examined after this initial request has been addressed.

VIII. REVIEW OF FUTURE MEETINGS ARRANGEMENTS

1. Scientific Council, (in conjunction with NIPAG), 9 – 16 Sep 2015

Scientific Council noted that the Scientific Council shrimp advice meeting will be held at the Northwest Atlantic Fisheries Centre, Newfoundland, 9-16 September in advance of the 2015 Annual Meeting. The Council noted the NAFO stocks will be addressed first so that the advice will be available to NAFO Contracting Parties on Monday, 14 September, a week in advance of the Annual Meeting.

2. Scientific Council, 21 – 25 Sep 2015

Scientific Council noted the Scientific Council meeting will be held at the Westin Hotel in Halifax, Nova Scotia, 21-25 September 2015.

3. Scientific Council, June 2016

Scientific Council agreed that its June meeting will be held on 3 – 16 June 2016, at St Mary's University, Halifax.

4. Scientific Council (in conjunction with NIPAG), Sep 2016

This meeting will be held ICES Headquarters, Copenhagen, around 7 – 14 September 2016.

5. Scientific Council, Sep 2016

Scientific Council noted that the Annual meeting will be held in September in Halifax, Nova Scotia, unless an invitation to host the meeting is extended by a Contracting Party.

6. Scientific Council, June 2017

Scientific Council agreed that its June meeting will be held on 2 - 15 June 2017.

7. NAFO/ICES Joint Groups

a) NIPAG, 9-16 Sep 2015

Scientific Council noted the NIPAG meeting will be held at the Northwest Atlantic Fisheries Centre in St. John's, Newfoundland, 9-16 September 2015.

b) NIPAG, 7 – 14 Sep 2016

This meeting will be held at the ICES Headquarters, Copenhagen, 7 – 14 September 2016.

c) WG-DEC, 15 – 19 February 2016

The next meeting of the ICES – NAFO Working Group on Deepwater Ecosystems is scheduled to take place at ICES Headquarters, during 15 – 19 February 2016.

. . .

The Working Group on Ecosystem Science and Assessment will meet at the NAFO Secretariat, Dartmouth, Nova Scotia, Canada, 17 - 26 November, 2015.

66

e) WG-HARP, August 2016

WG-HARP will continue its work by correspondence. The next meeting of the ICES – NAFO Working Group on Harp and Hooded Seals is scheduled to take place in during August 2017.

IX. ARRANGEMENTS FOR SPECIAL SESSIONS

1. Proposals for Future Special Sessions

There were five proposals for symposia. These will be circulated and discussed in September.

X. MEETING REPORTS

1. Working Group on Ecosystem Science and Assessment

The Scientific Council Working Group on Ecosystem Science and Assessment (WGESA), formerly known as Working Group on Ecosystem Approaches to Fisheries Management (WGEAFM), met at the NAFO Headquarters, Dartmouth, Canada, on November 18-27, 2014. The detailed outcomes of this meeting are reported in SCS 14/023.

WGESA currently operates within a set of long-term Themes and Terms of Reference (ToR) which are being systematically addressed by the group over several meetings. These Themes and ToRs build on the *"Roadmap for Developing an Ecosystem Approach to Fisheries for NAFO"* (Roadmap).

Following a request by the SC chair, WGESA organized its work for this meeting so to provide input towards addressing 3 ecosystem-related Fisheries Commission requests (FC Requests # 4, 11, and 12). These FC requests were integrated into the long-term ToRs.

The final form of the ToRs addressed at the 7th WGESA meeting were:

Theme 1: Spatial considerations

ToR 1. Update on identification and mapping of sensitive species and habitats in the NAFO area.

ToR 1.1. Update on Vulnerable Marine Ecosystem (VME) data analyses and VME distribution analyses in relation to ecoregions and VME elements.

ToR 2. Based on available biogeographic and ecological information, identify appropriate ecosystem-based management areas.

ToR 2.1. Final results on integrated Northwest Atlantic ecoregions analysis

Theme 2: Status, functioning and dynamics of NAFO marine ecosystems.

ToR 3. Update on recent and relevant research related to status, functioning and dynamics of ecosystems in the NAFO area.

ToR 3.1. Analysis on benthic communities in Flemish Cap and NL

ToR 3.2. Progress on expanded single species, multispecies and ecosystem production potential modelling

ToR 3.3. Progress on multispecies and ecosystem analyses

Theme 3: Practical application of ecosystem knowledge to fisheries management

ToR 4. Update on recent and relevant research related to the application of ecosystem knowledge for fisheries management in the NAFO area.

ToR 4.1. *[FC Request #4]* Work towards the development of assessments of bottom fishing activities (e.g. distribution modelling, classification of fisheries, ecosystem background, template for risk analysis, and advance on assessment of significant adverse impacts on VMEs).

ToR 4.2. *[FC Request #11]* Review of existing information on the potential impacts of activities other than fishing (e.g. oil and gas, shipping, recreation), and the risks they may pose, for the stocks and fisheries for which NAFO is responsible as well as biodiversity in the NAFO Regulatory Area.

67

ToR 4.3. *[FC Request #12]* Review of information and analyses on the impact of mid-water trawls on VME indicator species in those instances when the gear makes contact with or is lost on the bottom.

ToR 5. Methods for the long-term monitoring of VME status and functioning.

ToR 5.1. Update of the NAFO Guide of the Identification of Vulnerable Marine Ecosystem (VME) indicator taxa.

Theme 4: Specific requests

ToRs 6+. As generic ToRs, these are place-holders intended to be used when addressing expected additional requests from Scientific Council.

ToR 6.1. Evaluation of Research Vessel (RV) surveys footprint on VME closures.

In addressing ToR 1, WGESA continued the analysis of data emerging from the NEREIDA program, and updated VME information from the EU survey. The NEREIDA-based studies included the analyses of box-core data, which involved the identification of species assemblages, and the analysis of relationships between these assemblages and environmental variables. These studies identified VME and non-VME assemblages, and further confirmed the presence of VME assemblages within the areas currently protected through closures.

In addressing ToR 2, WGESA carried out an integrated ecoregion analysis at the scale of the East coast of North America (Newfoundland and Labrador Shelves, Flemish Cap, Scotian Shelf, and US northeast continental Shelf -Gulf of Maine, Georges Bank, and Mid-Atlantic Bight-) Northwest Atlantic, and review the results in the context of previous regional ecoregion analyses and other ecological studies. As part of this work, WGESA identified three nested spatial scales (bioregion, ecosystem production unit, and ecoregion) considered relevant and useful for the development of ecosystem summaries and management plans, and proposed the intermediate scale, the Ecosystem Production Unit (EPU), as the focal spatial scale for defining Ecosystem-based Management units. Using results from these analyses, as well as expert opinion, WGESA defined and put forward a set of consensus EPUs as candidate areas for the implementation of the Roadmap.

In addressing ToR 3, WGESA made progress on the analysis of epibenthic invertebrate megafaunal communities in the tail of the Grand Bank and Flemish Cap, the development of Ecosystem Production Potential (EPP) models and estimation of Fisheries Production Potential (FPP), as well as on several modelling and ecosystem analyses and updates, which included status reports on the modelling work on Greenland halibut in Greenland, multispecies modelling in the Flemish Cap, the use of ecosystem indicators to define ecosystem state, and updates on ecosystem and community trends, diets of key fish species, stable-isotope studies, and marine mammal studies in the Newfoundland and Labrador (NL) shelves. Within this ToR, the work on EPP models and FPP estimates derived from them was deemed mature enough to be used for the proposal of guidelines for Total Catch Ceilings in some EPUs where stocks are managed by NAFO (Northeast Newfoundland shelf, Grand Bank and Flemish Cap). Although refined versions of the EPP models are being developed, current estimates of FPP were considered adequate to start the conversation with fisheries managers about the implementation of Tier-1 (Total Catch Ceilings at the ecosystem level) in the context of the Roadmap.

In addressing ToR 4, WGESA developed the material required by Scientific Council (SC) to address three Fisheries Commission (FC) requests. The work towards addressing FC Request #4 involved the continuation of the development of tools and approaches required to do the reassessment of bottom fishing activities pertaining their impact on VMEs; this included the development of a template for the assessment, the definition and description of fisheries in the NRA, the compilation of information to describe the marine community, the further development of the approach to evaluate risk of Significant Adverse Impact (SAI) on VMEs, and the consideration of this approach in the context of formal Risk Assessments frameworks. The work towards FC Request #11 involved a literature review and summary aimed to identify potential risks to fish stocks and ecosystems in the NRA from activities other than fishing. With regard to FC Request #12, WGESA work summarized available information on the impact of midwater trawls on VMEs; results

corroborated earlier advice provided by SC in 2010 which indicated that midwater trawls can have an impact on VMEs, especially in seamounts.

68

In addressing ToR 5, WGESA worked collaboratively with the NAFO Secretariat to produce a second version of the NAFO Guide for the identification of VME indicator taxa, and agreed on which taxa should be added to the new edition of the guide.

In addressing ToR 6, evaluation of research vessel (RV) surveys footprint on VME closures, WGESA encountered unexpected problems with data formats which prevented the WG to fully engage this work. Due to time limitations, WGESA referred the treatment of this topic back to Scientific Council for its assessment during SC June meeting in 2015.

Following the ongoing cross-attendance practice, the co-chair of the ICES Working Group on the Northwest Atlantic Regional Sea (WGNARS), Robin Anderson, attended the 7th WGESA meeting, presenting a summary of the work done by ICES WGNARS in its 2014 meeting, as well as recent progress in the implementation of the Galway Statement within Canada.

WGESA also discussed next step and future activities. It was proposed that the 8th WGESA meeting to take place in November 17-26, 2015, at the NAFO Secretariat in Dartmouth, Canada. WGESA proposed to continue addressing its long-term ToRs, focusing the work during the 8th meeting as follows:

Theme 1: Spatial considerations

ToR 1. Update on identification and mapping of sensitive species and habitats in the NAFO area.

• Update on VME data and VME distribution analyses.

ToR 2. Based on available biogeographic and ecological information, identify appropriate ecosystem-based management areas.

• No expected work on this ToR.

Theme 2: Status, functioning and dynamics of NAFO marine ecosystems.

ToR 3. Update on recent and relevant research related to status, functioning and dynamics of ecosystems in the NAFO area.

- Analysis on benthic communities
- Progress on expanded single species, multispecies and ecosystem production potential modelling
- Progress on multispecies and ecosystem analyses

Theme 3: Practical application of ecosystem knowledge to fisheries management

ToR 4. Update on recent and relevant research related to the application of ecosystem knowledge for fisheries management in the NAFO area.

• Assessment of bottom fishing activities pertaining to the impacts on VMEs

ToR 5. Methods for the long-term monitoring of VME status and functioning.

• Preliminary results on the use of non-destructive sampling to monitor VMEs

Theme 4: Specific requests

ToRs 6+. As generic ToRs, these are place-holders intended to be used when addressing expected additional requests from Scientific Council.

WGESA co-chairs informed SC of their intention of stepping down from their positions at the SC September meeting in 2016. By this date, both co-chairs would have been in their position for eight years.

Scientific Council considerations

Scientific Council took notice of the progress made by WGESA, and approved the plans for the next meeting in November 17-26, 2015 at the NAFO Headquarters. On the basis of the WGESA work, SC further examined the

ecoregion and EPP/FPP analyses (including the Guidelines for Total Catch Ceilings), and agreed to put these elements forward to FC/SC WGEAFFM for consideration towards the implementation of the Tier-1 of the Roadmap (i.e. definition of ecosystem-level management areas, and setting Total Catch Ceilings at the ecosystem level). With regards of the reassessment of bottom fishing activities pertaining their impact on VMEs, SC recommended WGESA to further consider the role of environmental variables to define the fine scale features of VME boundaries, and to take into account the VME areas outside the NAFO fisheries footprint in the calculation of the VME area not exposed to risk of Significant Adverse Impacts.

69

Advances towards the implementation of an Ecosystem Approach to Fisheries for NAFO

NAFO is committed to apply an ecosystem approach to fisheries management in the Northwest Atlantic that includes safeguarding the marine environment, conserving its marine biodiversity, minimizing the risk of long term or irreversible adverse effects of fishing activities, and taking account of the relationship between all components of the ecosystem. The process and guiding principles that NAFO is following to achieve this goal is summarized in the organization's "Roadmap for developing an Ecosystem Approach to Fisheries for NAFO" (Roadmap). The Roadmap (Fig. 1) provides an operational perspective of how the Ecosystem Approach to Fisheries (EAF) is being conceived in a work-flow process that suits NAFO structure and practices.

The Roadmap follows a 3-tier, hierarchical process to delineate sustainable fishing activities (Fig. 7). The first tier defines fishery harvest potential at the ecosystem level, taking into account environmental conditions and ecosystem state. This allows consideration for the potential influence of large scale climate/ecological forcing, and the relation between primary production and ecosystem productivity. The second tier utilizes multispecies models that take into account species interactions as well as considerations on the resilience and stability of the exploited assemblage. This tier explicitly considers the trade-off among fisheries, and aims to identifying exploitation rates which are consistent with multispecies sustainability. The third tier involves single-species stock assessment, where the exploitation boundaries derived from tiers 1 and 2 can be further examined to ensure single-species sustainability.

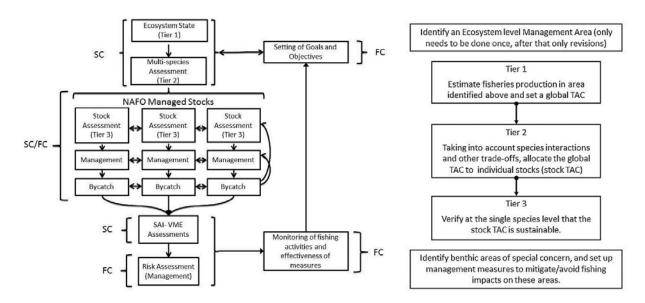

Fig. 7. Current working template of the NAFO "Roadmap" (left), with a synoptic overview of the key steps required for using it (right). SC: Scientific Council, FC: Fisheries Commission, SAI: Significant Adverse Impact, VME: Vulnerable Marine Ecosystem

The "Roadmap" can be implemented in a modular fashion as its different components are developed, in line with the priorities set out by FC-SC WGEAFFM (FC-SC Doc. 14/03). Existing examples of this modular approach towards the implementation of the Roadmap have been the identification of VME indicator taxa and elements, the delineation of VMEs by SC, and the closures for their protection implemented by FC.

At the present time, some of these other components are considered mature enough to begin the conversation between managers and scientists towards their implementation. These elements include the definition of Ecosystem-level management areas, and the establishment of total catch ceilings for these areas.

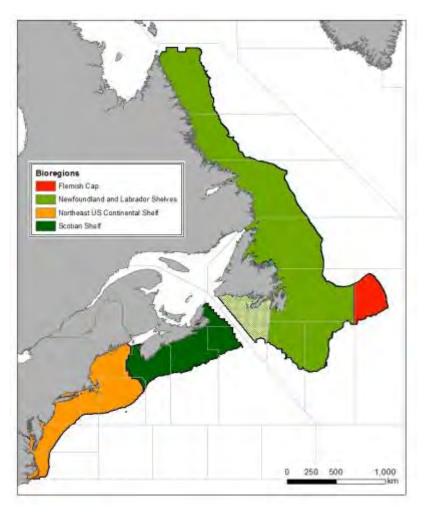

Spatial scales and candidate areas for ecosystem-level summaries and management plans

A necessary element for implementing an Ecosystem Approach to Fisheries is to identify the region in space that, in practice, bounds the ecosystem that is intended to be managed in an integrated way. In this context, a series of spatial analyses, typically referred as "ecoregion analyses", have been carried out looking at delineating and describing the spatial organization of several marine ecosystems in NAFO Convention Area, and consequently, identifying spatial scales that would be useful for ecosystem-level summaries and management plans (NAFO 2010a, 2010b, 2011, 2012, 2013, 2014). These studies have encompassed analyses at the regional level (e.g. Northeast Newfoundland Shelves, Flemish Cap, Scotian Shelf, Northeast US Continental Shelf) (Fogarty and Keith 2009 – unpublished; Pepin *et al.*, 2010, 2012; Pérez-Rodriguez *et al.*, 2010; Zwanenburg *et al.*, 2010), explored the variability of the delineated areas over time (Pepin *et al.*, 2012, NAFO 2012), as well as integrated across the East coast of North America (Pepin *et al.* in prep, NAFO 2014).

All these analyses followed a similar general rationale (i.e. principal component analysis (PCA) to reduce dimensionality, followed by cluster analysis of the PCA scores to define areas), although some details and data layers have differed depending on either regional availability of data, or the need to integrate different regions within the integrated large scale analyses (NAFO 2010a, 2010b, 2011, 2012, 2013, 2014). The data layers used in these analyses typically included bathymetry, sea surface temperature, bottom temperature, Chlorophyll-a and primary production derived from satellite information, as well as total demersal biomass and diversity derived from RV surveys; distribution of corals and sponges, fish taxonomy, surficial geology, nekton biomass, among others has also been considered in some of the regional analyses, while the integrated large-scale study involved analyses with and without geographical proximity as a constraint (NAFO 2010a, 2010b, 2011, 2012, 2013, 2014)

Three major spatial scales could be considered for the development of ecosystem summaries and management plans were identified (Table 2).

On the broadest scale is "bioregions" which identifies Newfoundland and Labrador Shelves, Flemish Cap, Scotian Shelf, and US northeast continental Shelf (Gulf of Maine/Georges Bank/Mid-Atlantic Bight).

71

Fig. 8. Bioregions identified by multiple "ecoregion analyses", as well as expert opinion. NAFO Div. 3P appears shaded because it is considered part of the NL shelves, but data for this area were not included in the ecoregion analyses.

Within the bioregions the Ecosystem Production Units (EPUs) define one or more major areas which contain a reasonably well defined food web/production system; these areas provide the spatial scale with which to estimate fishery production potential (Fig. 9). Although EPUs are proposed as candidate management units, it should not be assumed that they are fully closed systems; transfer of production across EPU boundaries within a bioregion is to be expected. Whenever possible, these transfers should be estimated and considered when setting catch levels, but until those estimates are available, attention to the Ecosystem Production Potential (EPP) and Fisheries Production Potential (FPP) of neighbouring EPUs should be paid when developing ecosystem-level management plans.

Finally, each of the EPUs consists of a combination of ecoregions, which represent elements with different physical and biological characteristics based on the analytical criteria applied. Ecoregions in themselves do not define all ecologically important elements but that instead represent an intermediate level of delimitation of ecosystem elements in a hierarchy of spatial scales. It is the ecoregion scale, the one expected to provide the context for defining more precise habitats, including Vulnerable Marine Ecosystems (VMEs). Management measures aimed at the ecoregion scale would be better informed from the regional analyses because those analyses include more local data sets (Fogarty and Keith, 2009 – unpublished; Pepin *et al.*, 2010, 2012; Pérez-Rodriguez *et al.*, 2010; Zwanenburg *et al.*, 2010). Fig. 10 provides an illustration of the ecoregion scale from the integrated analysis.

Scientific Council endorsed the following EPUs as Ecosystem-level Management Areas for use in a pilot implementation of EAF: Flemish Cap (Div. 3M), the Grand Bank (Divs 3LNO), and the Northeast Newfoundland Shelf (NAFO Divs. 2J3K).

SC further notes that these proposed management areas capture the core of the underlying ecosystem production units, but also respect, whenever feasible, existing management boundaries; this should allow for an easier transition from current single-species management practices into more integrated ecosystem-based approaches by leveraging as much as possible on existing databases, assessments, and management procedures.

Name	General operational description	Examples in NAFO Convention Area	
Bioregion	Large geographical area characterized by distinct bathymetry, hydrography, and which contains one or more reasonably well defined (but still interconnected) major marine communities/food web systems.	 Newfoundland and Labrador Shelves Flemish Cap Scotian Shelf US northeast continental Shelf 	
Ecosystem Production Unit (EPU)	Within a bioregion, a major geographical subunit characterized by distinct productivity and a reasonably well defined major marine community/food web system.	 Northeast Newfoundland Shelf (2J3K) Grand Bank (3LNO) Flemish Cap (3M) Georges Bank 	
Ecoregion	Within an EPU, geographical area with consistent physical and biological characteristics. Often corresponds to a broadly defined seascape and/or major habitat type/class; its precise delineation and extent can vary depending on data availability and the analytical criteria applied. It is within this spatial scales that more precise habitats can be identified (e.g. VMEs).	 Inshore areas in the Northeast Newfoundland Shelf North region of the Grand Bank (~3L) Top of the bank in Flemish Cap Slope areas 	

 Table 2.
 Basic spatial scales identified for ecosystem summaries and management plans in the context of developing and implementing Ecosystem Approaches to Fisheries Management.

<u>.</u>

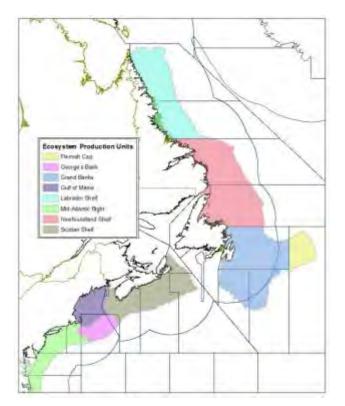

Fig. 9. Ecosystem Production Units (EPUs) identified as a result of multiple "ecoregion analyses" and expert opinion. These areas are proposed as candidate Ecosystem-level Management Areas.

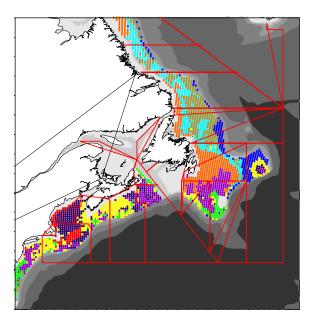

Fig. 10. Ecoregions from the integrated analysis. Each colour represents a different cluster, and illustrates the spatial scale associated with the ecoregion level as described in Table 2. These ecoregions are for illustrative purposes only, management measures aimed at the ecoregion scales are recommended to rely on regional analyses.

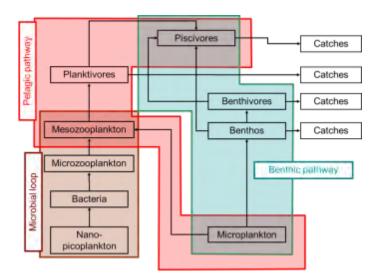

Total maximum catch potential in an ecosystem, can be estimated by Ecosystem Production Potential (EPP) models (NAFO 2012, 2013, 2014, Koen-Alonso *et al.*, 2013). This upper limit of fishing exploitation is referred to as Fisheries Production Potential (FPP). This approach is consistent with analyses done by FAO to estimate global fisheries production potential (Rosenberg *et al.*, 2014). However, FPP estimates assume that the ecosystem is fully functional, and that all the primary production in the system is effectively transferred to the rest of the food web. This assumption may be reasonable in some cases, but not in others. Therefore, defining ecosystem level ceilings using FPP estimates also requires assessing if this assumption holds; if not, the actual ecosystem level ceiling would be some fraction of FPP.

The Ecosystem Production Potential (EPP) model

The EPP model is a simple food web model that describes the flow of energy in the ecosystem where the basic input of primary production estimated from satellite data is transferred up the food web (Koen-Alonso *et al.*, 2013, Rosenberg *et al.*, 2014, Fogarty *et al.*, in press) (Fig. 11).

Following Iverson (1990), the ratio of new primary production to total primary production was used as upper limit for exploitation at the ecosystem level (i.e. a limit reference point); this parameter was approximated by the ratio of microplankton production to total primary production. On this basis, exploitation rates of 20-30% were selected as limit reference points for exploitation (Iverson, 1990, Rosenberg *et al.*, 2014). These exploitation rates were used to derive initial FPP values, but in the case of benthos and planktivores, further reductions to the estimated FPPs were applied by considering that many species included in these groups are not currently of commercial value. It was assumed that only 10% of the benthos and 50% of the planktivores production were of interest to harvesters.

Production of benthivores and piscivores (Fig. 4) was also combined to better reflect the overall fisheries production potential of demersal species as a generic target group for fisheries. It is important to highlight that these Standard Demersal Components (SDC) include traditional commercial groundfish species like Atlantic cod and American place which may vary in their reliance on benthos as they grow, but also commercial shellfish like shrimp and snow crab. The amalgamated SDC group is better suited for comparisons with catch levels which are often dominated by groundfishes and shellfish, and because a number of piscivorous species also prey on benthic organisms and have broadly omnivorous feeding patterns.

75

Fig. 11. Ecosystem Production Potential (EPP) model structure. Nano-picoplankton, bacteria, and microzooplankton comprise the microbial food web in this representation. The classical grazing food web is fuelled by microplankton production and is represented by the pelagic and benthic pathways. Species characterized by ontogenetic shifts in diet and/or mixed feeding strategies can occupy multiple compartments in this representation.

Estimates of Fisheries Production Potential densities

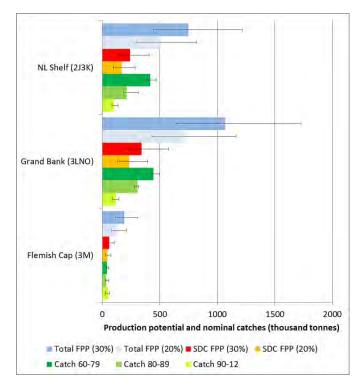

The two exploitation rates considered as limit reference points in this analysis indicated total FPP densities of around 2-3 tonne/km², with a general variability ranging around 1-5 tonne/km². These figures compared well with Maximum Sustainable Yields (MSYs) obtained from aggregate biomass production models for a suite of marine ecosystem (Bundy *et al.*, 2012). These aggregate MSYs rendered values in the order of 1-5 tonne/km², which is remarkably consistent with the figures obtained here, and suggests that the estimated magnitudes are likely robust ones.

The estimated FPP densities for SDC components were around 0.6-1 tonne/km², while their variability ranged around 0.4-2 tonne/km². The dominant factor in the difference between total and SDC estimates is the contribution of planktivores (e.g. forage fishes) to the total FPP, although the benthos contribution is not trivial.

Guidelines for Total Catch Ceilings for the Flemish Cap, the Grand Bank, and the Northeast Newfoundland Shelf

The existing version of the EPP models for the Flemish Cap, the Grand Bank, and the Northeast Newfoundland Shelf EPUs are considered adequate to start providing advice for total catch ceilings for these areas. Taking into account that this is the first attempt to explore these models and results in a management context, it is important to highlight the "proof of concept" nature of this process within the pilot exercises proposed. In this initial stage, these estimates are intended to help managers to begin assessing how current catch levels measure up to this additional management dimension, as well as stimulate the dialogue on how best to implement this new ecosystem-level limit reference point.

As part of this process it is relevant to compare historical catch levels with estimated FPPs (Fig. 12). These comparisons indicate that the total FPP for these ecosystems was never realized, but when catches are compared with SDC FPP, they clearly indicate that catches in the Northeast Newfoundland Shelf and Grand Bank EPUs were much higher than what these systems can sustain, while the Flemish Cap EPU saw catches at the level of its SDC FPP (Fig. 12). Considering that most catches in these ecosystems are demersal species, the comparisons with SDC estimates are more meaningful for understanding the potential impacts of fishing in these systems. On this basis, the Northeast Newfoundland Shelf and Grand Bank EPUs were clearly over-exploited at the ecosystem level in the past, while the Flemish Cap was exploited at its limit.

76

Fig. 12. Comparison between catch levels and the corresponding fisheries production potential (FPP) for the Northeast Newfoundland Shelf, Grand Bank, and Flemish Cap Ecosystem Production Units (EPUs). Catch levels are characterized by the nominal total landings in three time periods (1960-1979, 1980-1989, and 1990-2012). Fisheries production potential is characterized by the estimated Total and SDC Fisheries Production Potential for these EPUs under a 20% and 30% ecosystem exploitation rates scenarios. Bars correspond to medians, while error bars correspond to the 25-75% quantile intervals.

Taking into account their histories of exploitation, and using the relative constancy of the biomass/abundance ratio, the total RV biomass in these systems was used to gauge their productivity state. In the Newfoundland Shelf and Grand Bank EPUs, current total fish biomass is estimated to be around 40-50% of the pre-collapse levels (NAFO 2013, 2014). This indicates that the changes experienced by these systems eroded their production capacity, which remains impaired to this date. Therefore, ecosystem-level catch ceilings for these EPUs should be set at some fraction of the estimated FPP. For these two systems a fraction of 50% was applied to calculate the guideline values for total catch ceilings.

Unlike the Newfoundland Shelf and Grand Bank EPUs, the total biomass of the Flemish Cap ecosystem is currently at or above the levels observed prior to the collapse in the early 1990s. This total biomass level do not suggest that the overall productive capacity of this system is impaired, and hence, there is no need to apply a penalty factor to the FPP estimate to calculate a guideline value for total catch ceiling in this ecosystem.

Based on the above considerations, guideline values for total catch ceilings in the Newfoundland Shelf, Grand Bank, and Flemish Cap are summarized in Table 3.

Northwest Atlantic Fisheries Organization

Table 3.Guideline values for total catch ceilings for the Newfoundland Shelf (NAFO Divs 2J3K), Grand
Bank (NAFO Divs 3LNO), and Flemish Cap (NAFO Div. 3M) Ecosystem Production Units
(EPUs). These guideline value correspond to the estimated Fisheries Production Potential
(FPP) for these systems; FPP is presented as Total (Piscivores+ Benthivores + Planktivores +
Benthos), and Standard Demersal Components (SDC) (Piscivores + Benthivores). FPP
estimates were derived considering ecosystem exploitation rates of 20% and 30%. A 50%
penalty factor was applied to the Newfoundland Shelf and Grand Bank EPUs due to current
ecosystem state. Median nominal landings for different time periods are also shown for
comparative purposes; these nominal landings coarsely correspond to SDC species.

77

	Median Fisheries Production Potential (FPP) (thousand tonne/yr)				Median Total Nominal Landings (thousand tonne/yr)		
	Total FPP (20%)	Total FPP (30%)	SDC FPP (20%)	SDC FPP (30%)	1960-1979	1980-1989	1990-2012
Newfoundland Shelf (2J3K)	253	374	85	121	416	210	102
50% penalty applied							
Grand Bank (3LNO)	257	534	117	171	446	304	119
50% penalty applied	357						
Flemish Cap (3M)	129	192	43	62	42	34	53

The Standard Demersal Components (SDC) is the subset of FPP that coarsely correspond to the species traditionally targeted by fisheries in these ecosystems. The comparisons between SDC guideline ceiling values and catches indicate that, for these three ecosystems, current exploitation is above their median SDC values under a 20% ecosystem exploitation rate, but still below the estimates under a 30% exploitation rate (Table #.2). Although these values are only guidelines and refinements are to be expected, these initial results are deemed robust enough to warrant attention. They indicate that current catch levels are at the limit of what these ecosystems can sustainably tolerate. In this context, it would be advisable that any increase in Total Allowable Catch for a given stock should be compensated with a decrease in another, in order to avoid a net increase in total catches. Increasing total SDC catches could lead to ecosystem over-exploitation, potentially eroding the ecosystem productive capacity in the case of the Flemish Cap, and preventing (or even reverting) the current recovery/build-up being observed in the Newfoundland Shelf and Grand Bank.

These guidelines constitute a step forward towards implementing the 3-tier process described in the Roadmap to achieve sustainability of fisheries exploitation. Further refinements on this component are expected as work progresses. Current work involves improvements in the structure of the basic EPP model, as well as more detailed matching between target species with the FPP components (e.g. which species should be considered SDC, and which ones may be better classified as planktivores or benthos). Other elements also expected to inform this component in the future include updated versions of aggregate biomass production models for these systems (NAFO 2012, Bundy *et al.*, 2012).

2. ICES-NAFO Working Group on Deepwater Ecosystems (WGDEC)

On 16th February 2015, the joint ICES/NAFO WGDEC, chaired by Neil Golding (UK) and attended by fourteen members (eleven in person, three via WebEx) met in Horta, Faial, Azores. WGDEC was requested to provide all new information on the distribution of vulnerable marine ecosystems (VMEs) in the North Atlantic.

A total of 510 new records were brought to the group this year and appended to the VME database. The new data were from a range of sources including fisheries surveys and seabed imagery surveys. No recommendations were made for the modification of existing, or creation of new bottom fishing closures.

Within the NEAFC regulatory area, the following areas were considered:

• Rockall Bank: new VME indicator records from two scientific fish stock assessment surveys were made available. In addition, new information was provided from a commercial fishery but no bycatch was recorded.

Within the EEZs of various countries the following areas were considered:

- Rockall Bank: new VME indicator records from two scientific fish stock assessment surveys were made available.
- Rosemary Bank: The group considered new VME indicator bycatch records from a scientific trawl survey. Towed video imagery from the same survey also showed evidence of the VME habitat type 'deep-sea sponge aggregations.'
- Faroe-Shetland Channel: new VME indicator records from a scientific trawl survey were presented to WGDEC.
- Bill Baileys Bank and Lousy Bank: New information on VME indicator bycatch records was provided from a commercial fishery.
- Greenland: The group considered a new record of the habitat type 'cold water coral reef', verified by drop down video.
- Portugal: WGDEC 2015 was made aware of new VME indicator records from within Azorean waters published in a scientific paper. Data from this scientific paper were not provided to WGDEC and are not currently within the VME database.

Within the Northwest Atlantic (NAFO regulated) the following areas were considered:

• Flemish Cap Bank, Grand Banks and Flemish Pass Basin: New information on VME indicator bycatch records was provided from a commercial fishery.

WGDEC used VMS-data for 2014 to analyse the spatial distribution of bottom fishing activity in the NEAFC Regulatory Area. Speed filtering for bottom fishing gear types was improved from last year using vessel speed histograms. WGDEC examined the general data distribution and also looked at some areas in greater detail, such as Hatton and Rockall Banks, Mid-Atlantic Ridge and Josephine seamount. WGDEC sought to further develop the system developed in 2014 to weight the reliability and significance of VME indicator records. The main advance this year was to move from viewing individual points in the VME indicator database to a spatially gridded data format, which also combined the geographical locations of VMEs in close proximity to each other. The new system captured the fact that not all 'VME indicator species' within the VME database have the same vulnerability to human impacts. Additionally, to account for data quality issues, a 'data uncertainty' index was developed. A proposal for a novel methodology for combining isolated occurrences of VME indicator records into a single bottom fishing closure was submitted to WGDEC 2015; this proposal needs further consideration at WGDEC 2016. WGDEC also recommend that in 2016, the work achieved under this ToR (b) is consolidated with previous work undertaken by WGDEC with respect to buffer zones in order to develop a set of guiding principles for delineating bottom fishing closure boundaries. WGDEC discussed progress with developing the VME database. This database provides an essential resource for the some of the core work of WGDEC. The large number of 'restricted' records within the database was discussed and proposals made to address this issue. Developments with the ICES VME data portal made since WGDEC 2014 were also discussed. Some clarifications to the VME database guidance were discussed and agreed. Finally, WGDEC discussed and agreed to progress a VME data call pilot, in conjunction with the ICES Data Centre. The VME Data Call would invite ICES Member Countries to submit new data on occurrences of VME indicators or VME habitat types for use in WGDECs work. WGDEC discussed the potential impacts of deep-sea mining on vulnerable deepwater habitats. WGDEC reassessed the Pressures List developed through the OSPAR Intercessional Correspondence Group on Cumulative Effects (ICG-C), a subgroup of the Environmental Impacts of Human Activities (EIHA) committee, and suggested some modifications to ensure that the pressures associated with deep-sea mining activities were adequately covered. WGDEC noted that as deepsea mining has not begun and many of the potential impacts, such as extent of plumes and toxicity levels, remain unknown. It is therefore very difficult to predict the sensitivity of vulnerable marine habitats to these potential impacts and so fully address this Terms of Reference at this time. WGDEC reviewed new evidence of ecosystem functioning on VME indicators in the North Atlantic in relation to the CORALfish project and other

3. Joint FC-SC Working Group on Risk Based Management Strategies (WG-RBMS)

The co-chair Carsten Hvingel presented the report of WG-RBMS to the Council. Two important items on the agenda of importance to SC was highlighted in particular, the revision of the NAFO Precautionary Approach framework (item 5) and the development of the Div. 3M cod management plan (item 7). Item 5: It was noted that the NAFO PA framework and the NAFO management and advisory practice does not line up and that a revision is indeed needed. It was however recognized that the complexity of the technical aspects involved would be better handled by a smaller technical group formed by SC and that FC should identify the scope for this work. Item 7. The WG reviewed results from a Management Strategy Evaluation process (MSE) for Div. 3M cod: none of the investigated Harvest Control Rules met management objectives and could therefore not be recommended to FC. The work will continue in close cooperation with SC. The report is available as NAFO FC/SC Doc. 15/02.

4. Report from ad hoc Joint Working Group on Catch Reporting (WG-CR)

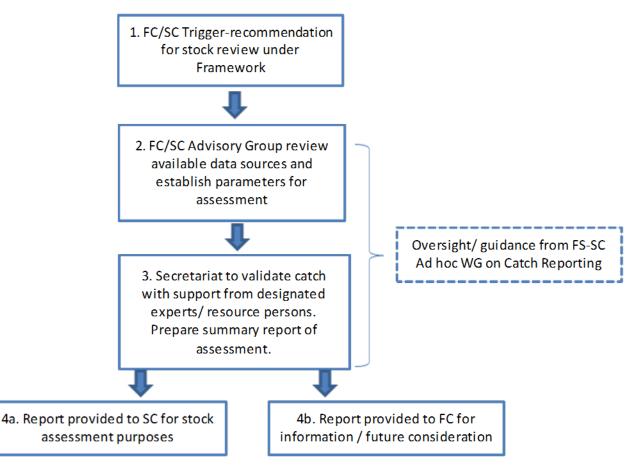

The Scientific Council Chair updated the Council on the proceedings of this meeting. The working group reviewed the Recommendations from its 2014 meeting. A broad recommendation is the establishment of a process for catch estimation using a suite of available data housed at the NAFO Secretariat and any other available data. To address this recommendation, a framework for the validation of the NAFO catch data and generation of catch estimates was discussed.

Towards the development of a framework a review of the available NAFO fisheries catch databases housed at the Secretariat was conducted. The tabulated evaluation would be considered a "living document" as it would be used as a guide and would be regularly reviewed and updated during the exercise of catch estimation and validation. It was noted that the VMS and CAT database and the haul-by-haul logbook data information are considered the primary source for catch validation information, with the former considered the most reliable and the latter useful for effort validation information.

The haul-by-haul logbook information is a new requirement for fishing vessels in 2015. Compliance issues concerning timely submissions and compatibility of the report format with NAFO IT systems were observed. The WG emphasized the importance of the format compatibility of the haul by haul reports and that this is an urgent issue that needs to be resolved.

Central to the development of the framework is the creation of Catch Data Advisory Group. The Terms of Reference (ToR) of the group were developed. The ToR specifies the composition of the group and outlines three priority stocks, noting the scheduled full assessment and development of the Management Strategy Evaluation for these stocks.

The operation of the Catch Data Advisory Group is described in Fig. 13. The Catch Reporting WG would function as an overseer of the Catch Data Advisory Group, while trying to minimize overlaps and the proliferation of intercessional work for Contracting Parties.

81

Fig. 13. Proposed workflow for Catch Data Advisory Group.

The WG agreed to operate for another year under the same goals and objectives as it did for this inaugural year. The WG went on to make a number of recommendations to the Fisheries Commission and Scientific Council. The report is available as NAFO FC/SC Doc. 15/01.

5. Meetings attended by the Secretariat

a) Coordinating Working Party on Fishery Statistics (CWP)

The intersessional meeting of the Coordinating Working Party on Fishery Statistics (CWP), Capture Fishery Subject Group meeting (CWP-FS) was held on 25-27 February 2015 in Swakopmund, Namibia. George Campanis (SEAFO), the Coordinator of the Fishery Subject Group, chaired the meeting, which was attended by seven experts from four CWP participating organizations (Eurostat represented by DG Mare, FAO, NAFO, SEAFO) and additional three participants from the Benguela Current Commission (BCC), Western Central Atlantic Fishery Commission (WECAFC) and South Pacific Regional Fisheries Management Organization (SPRFMO). The CWP participating organizations briefly reported their recent activities relating to fishery statistics. NAFO was represented by Neil Campbell (SC Coordinator) and Barbara Marshall (Senior Information Officer).

NAFO indicated it had made progress in four areas in addition to the regular update of statistics. First it has convened a joint science/management working group to review and make recommendations on the procedure for catch estimation, focused on Greenland halibut, cod and American plaice. Secondly, NAFO is reviewing its conversion factors to harmonize values across Contracting Parties. NAFO and EU have agreed on the harmonization of STATLANT reporting dates. NAFO has made vessel-transmitted information (daily catch reports) available to its Scientific Council. This was used to provide catch figures for scientific assessments in 2014 as a full set of STATLANT 21A was not available at the time of the meeting.

The CWP Secretariat summarized progress towards the revision of CWP Handbook. The importance of establishing global standards was outlined. The CWP has played an important role in establishing and maintaining global standards in fisheries statistics that are well accepted and utilized. By contrast, the contribution by CWP in setting standards in some areas, e.g. management data collection and scientific observer data, has been limited, even though the need to standardize have been consistently raised in previous CWP discussions. Despite different views on the extent of the CWP mandate to cover setting standards, the meeting agreed that the CWP should provide a forum for communication and a place to coordinate the harmonization amongst interested parties.

82

The meeting discussed the 2017 revision process of Harmonized Commodity Description and Coding System, commonly referred to as the Harmonized System (HS), of the World Custom Organizations was completed recently, and the revision of the Central Product Classification of the United Nations (CPC), an international classification of commodities and services delivered. The version 2.1 would include separation of wild and farmed products for primary fish products, taxonomic groups as comparable to HS, and distinction of products for non-food uses.

FAO summarized the current situation and remaining issues related to the fleet and fishing operation, including a description of fisheries. Coupled with this is the issue of identification of fisheries. The FAO explained that this agenda item had been proposed as tentative, awaiting the outcome of FIRMS FSC9. The initiative of developing Unique Identifiers (UIDs) for fish stocks and fisheries is documented in the FIRMS FSC9 report including document FIRMS/FSC9/2015/4a and received the support of FSC9. These UIDs will enable the creation of a registry of distinct stocks and fisheries as part of a Global record which will facilitate federation of, and reliable reference to, reported status and trends of stocks and fisheries across various sources.

The FAO explained that COFI had made a request for FAO to develop a general guideline to establish global traceability of fish and fishery products, FAO considers the landing as a unique opportunity to allocate unique product identifiers. FAO has made previous attempts to develop standards for trade certificates without success and it was recognized that the requirements of already existing systems may mean that only relatively loose guidelines would be possible for the near future. The meeting noted that only few organizations, including CCAMLR, CCSBT and ICCAT, currently implement a catch documentation scheme (CDS). The group agreed that establishment of a working group would be useful.

Items for Scientific Council:

The FAO informed its intention to conduct a questionnaire survey to collect data on conversion factors during 2015. This is the first survey since 1992-1993 and is aiming to collect the conversion factors on different stages of production, including those for landed weight. The group recommended that the FAO dispatch the questionnaire to regional organizations. Recognizing the wide variability of conversion factors according to processing methods, areas and species, it was considered important to keep all of the details on products together with conversion factors, in particular, for the case of standardized conversion factors. The meeting felt it was not pragmatic to develop a set of standard conversion factors corresponding to global standard classification of fish and fishery commodities.

Scientific Council noted that work on the standardization of conversion factors was reviewed in 2014, and agreed to forward the outcomes of this work to the CWP Secretariat.

1. The FAO sought opinions on maintaining FishStatJ, a stand-alone data extraction and aggregation tool, or replacing it with an equivalent web based application. Members indicated a general need for an on-line data extraction tool, and requested more time to consult.

The general consensus within Scientific Council was that, while some individuals may make use of this tool in other fora, the use of FishStat has been largely superseded as a platform in NAFO by the development of the STATLANT 21 web extraction tool.

b) Fisheries and Resources Monitoring System Steering Committee (FIRMS)

The ninth session of the Fisheries and Resources Monitoring System (FIRMS) Steering Committee (FSC9) was held at the Southeast Atlantic Fisheries Organisation (SEAFO) headquarters in Swakopmund, Namibia, 23–24 February 2015. The meeting was opened by Marc Taconet, FIRMS Secretary, and Barbara Marshall (NAFO),

the chairperson. NAFO was represented by the SC Coordinator, Neil Campbell. The chair welcomed FIRMS members, NAFO, SEAFO and the FAO and associate members and observers from the Western Central Atlantic Fisheries Commission (WECAFC), Benguela Current Commission (BCC), the South Pacific Regional Fisheries Management Organisation (SPRFMO) and Western Indian Oceans Fisheries Database (WIOFish).

83

The issues focused on by the group were:

- Increased membership: the meeting acknowledged SPRFMO's intention to join the partnership, as well as WIOFish's willingness to initiate discussions with the Southwest Indian Ocean Fisheries Commission (SWIOFC) towards a statute of associate partner. Strategic collaboration with large marine ecosystem (LME) initiatives and programmes is seen as a way to strengthen national reporting in FIRMS, and the Committee encouraged the developing of experience with the Caribbean and North Brazil Shelf Large Marine Ecosystems (CLME+) and Bay of Bengal Large Marine Ecosystem (BOBLME) (where the focus is on positioning FIRMS as tool to support adaptive fisheries management), and welcomed BCC's intention to follow a similar process.
- FIRMS support to the proposed project of a Global record of stocks and fisheries (a component of BlueBRIDGE), which will federate knowledge on status/trends of stocks and fisheries across various sources, and as such is expected to offer key services to stakeholders involved in "regional/global state of stocks indicators", as well as public and private actors involved in ecolabelling, traceability and sustainable fisheries.
- The renewal of the FIRMS website, which is expected to better serve expectations of the general public, in particular through the proposed stocks and fisheries maps viewer.
- The incoming chairperson is Dr Neil Campbell (NAFO) and vice chairperson Ms Nancy Cummings (WECAFC). FSC10 will be held in Rome in 2017, and a technical working group (TWG) might be organized in connection with the twenty-fifth session of the Coordinating Working Party on Fishery Statistics (CWP25) in February 2016.

c) FAO VME Practices and Processes

A workshop on VME Processes and Practices was organized by the FAO in Swakopmund, Namibia, 2 – 4 March 2015. Participants were drawn from the FAO, NEAFC, NAFO, SEAFO, SPRFMO, GCFM, SPC, SPRFMO and SIODFA. NAFO was represented by the SC Coordinator, Neil Campbell.

To facilitate understanding of the work that has been done globally in RFMOs, enable the sharing of experience among the regions and assist with the upcoming UNGA review on bottom fisheries in 2016 (UNGA Res. 66/68, para. 137), FAO is compiling a publication entitled *VME Processes and Practices in ABNJ* detailing the development of the assessment and management of VMEs in each region to date. This will form a sister volume to the *Worldwide Review of Bottom Fisheries in the High Seas* that was published by FAO in 2009. FAO also plans to update the latter publication using information covering the period 2007-2013.

The objectives of the workshop were:

- To present and discuss draft regional chapters on the VME process and practices,
- To outline revisions required for each chapter, and,
- To agree on a plan of work for completing the drafts and a deadline for publishing the document.

A draft of each chapter had been prepared by the FAO prior to the meeting, which was passed to the Secretariat and/or representative of the participating RFMOs to review, provide references and return to the FAO.

XI. REVIEW OF SCIENTIFIC COUNCIL WORKING PROCEDURES/PROTOCOL

1. General Plan of Work for September 2015 Annual Meeting

No new issues were raised that will affect the regular work plan for the September meeting.

2. Other matters

Issues surrounding the timing of STACFEN were raised. It was felt that the current scheduling of the standing committee on the first Monday of the Scientific Council meeting delayed the start of STACFIS. It was noted that the merging of STACFEN and WG-ESA has been discussed. Pending any decision on this, it was proposed

that the Council open on Friday and move straight to STACFEN. The SC and STACFEN chairs will explore this issue intersessionally.

84

XII. OTHER MATTERS

1. Designated Experts

The list of Designated Experts will be confirmed at the September meeting.

2. Stock Assessment Spreadsheets

It is requested that the stock assessment spreadsheets and input data be submitted to the Secretariat as soon after this June meeting as possible. The importance of this was reiterated by STACREC. The Secretariat will remind Designated Experts of this request by mid-July.

3. Scientific Merit Awards

In December 2014 it was announced that Fredric [Fred] Serchuk, senior science advisor and fisheries biologist at the Northeast Fisheries Science Center (NEFSC) and long-time NAFO Scientific Council member was intending to retire. The SC Executive Committee was requested to consider awarding Fred a Scientific Merit award. This suggestion was approved unanimously, and a certificate provided, to be presented at his retirement.

Serchuk received a B.Sc. degree from Cornell University, an M.Sc. degree from the University of Massachusetts, Amherst, and a Ph.D. from Michigan State University. He worked at the Woods Hole Laboratory of NOAA's Fisheries Service since September 1976, serving in various research, supervisory, and leadership positions. Fred was involved with NAFO for more than three decades, participating in various committees, working groups, and study groups since 1979. During 1996-2008, Fred was the U.S. representative on the Scientific Council and served on the editorial boards of the *Journal of Northwest Atlantic Fisheries Science*.

4. Budget Items

Review of the budget working paper was deferred to the September meeting.

5. Other Business

a) Election of Chairs

The council endorsed Kathy Sosebee (USA) as the incoming Scientific Council chair; Brian Healey (Canada) as vice-chair of Scientific Council and chair of STACREC, and Joel Vigneau (EU-France) as chair of STACFIS. Margaret Treble and Andrew Cogswell (both Canada) were re-elected as chairs of STACPUB and STACFEN, respectively. Scientific Council were informed that the co-chairs of WG-ESA planned to step down before the 2016 meeting.

XIII. ADOPTION OF COMMITTEE REPORTS

The Council, during the course of this meeting, reviewed the Standing Committee recommendations. Having considered each recommendation and also the text of the reports, the Council **adopted** the reports of STACFEN, STACREC, STACPUB and STACFIS. It was noted that some text insertions and modifications as discussed at this Council plenary will be incorporated later by the Council Chair and the Secretariat.

XIV. SCIENTIFIC COUNCIL RECOMMENDATIONS TO GENERAL COUNCIL AND FISHERIES COMMISSION

The Council Chair undertook to address the recommendations from this meeting and to submit relevant ones to the General Council and Fisheries Commission.

Specifically, Scientific Council discussed the recommendations of the joint Fisheries Commission – Scientific Council Working Groups Catch Reporting and on Risk-Based Management Strategies to provide feedback in order that these groups can continue to develop their work.

From the Working Group on Catch Reporting (FC-SC Doc. 15/01).

The Working Group **recommends**:

1. that SC and FC give consideration to the establishment of the Catch Data Advisory Group and adopt its Terms of Reference (Annex 3);

3. that SC and FC or an appropriate subsidiary body review the utility of data collection more generally, noting that some newer data sets provide more reliable and/ or timely information, making others redundant.

The Scientific Council responded:

The Council endorses the establishment of the Catch Data Advisory Group and its Terms of Reference,

From the Working Group on Risk Based Management Strategies (FC-SC Doc. 15/02).

The Working Group **recommends**:

1. Scientific Council convenes a technical working group which could explore the revision of the precautionary approach.

Scientific Council discussed the need for a revision to the PA framework and agreed in principle that the framework should be developed to incorporate more recent thinking on precautionary reference points. A core group was nominated to begin a discussion on terms of reference. Feedback on this issue will be sought from Fisheries Commission in September.

3. Scientific Council to give a high priority to development of reference points for all stocks which lack them.

The table presented in 2014 was updated in light of the most recent assessment, details of current work provided and timelines for future work.

Stock	B _{lim}	F _{lim}	B _{msy}	Comments

Thorny Skate in Divs. 3LNO

Limit reference points for thorny skate were investigated using ASPIC models, catch-resilience models, and empirical reference points from the Canadian spring survey (SCR Doc. 15/40). ASPIC models and catchresilience models were not accepted. In the absence of an accepted population model for thorny skate in Divs. 3LNO and Subdiv. 3Ps, a number of potential limit reference points, based on the survey index, were investigated. B_{msy} proxies based on B_{max} , as well as periods associated with high productivity were calculated (Fig. 14). The majority of these calculations yielded similar estimates for B_{msy} , and the associated B_{lim} , which is defined as 30% of the B_{msy} proxy, as outlined in the NAFO Precautionary Approach Framework. Limit reference points based on B_{loss} from the survey index were also considered. It was concluded that the most suitable proxy for B_{lim} was 63 000 t, which represents the lowest value (i.e. B_{loss}) for the Canadian spring survey conducted with the Campelen survey gear.

87

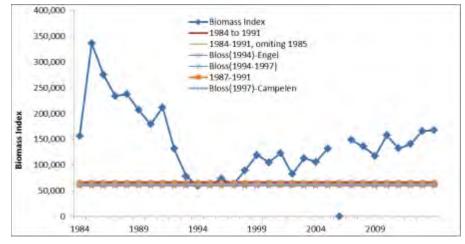

Fig. 14. Thorny Skate in Divs. 3LNO and Subdiv. 3Ps biomass index and various proxy limit reference points.

White Hake in Divs. 3NO

Limit reference points for white hake were investigated using Bayesian surplus production models, catchresilience models and empirical reference points from the Campelen survey series (SCR Doc. 15/40). Resulting limit reference points were not accepted due to uncertainty in how to apply them to a population with episodic recruitment.

Redfish in Div. 30

A model for Div. 30 redfish was tested during 2013, but it was not accepted. Work on developing a model for Div. 30 redfish, and exploration of empirical survey methods to determining limit reference points will continue.

Greenland halibut in SA 0+1

A number of age based and production based models have been attempted in order to estimate reference points in the past but they have all failed due to either problems with age determination or short time series with little contrast.

Roundnose grenadier in SA 0+1

SC is not in a position to determine biological reference points for roundnose grenadier in SA 0+1. Previously STACFIS has considered a survey estimate of 111 000 tons from 1986 as $B_{virgin.}$ However, given that roundnose grenadier is a long living species and that fishery stopped around 1979, it is uncertain whether the stock could be considered as virgin in 1986. Although the biomass estimates from the 80s and early 90s are not directly comparable with recent estimates these are far below what was seen previously. The survey time series from the 80s and the early 90s are, however, too short to be used for estimation of reference points.

There was an attempt to set reference points for Greenland halibut in SA 2+ Divs. 3KLMNO using F_{max} as a proxy for F_{msy} , however, this was not accepted at the time because of the stock history relative to F_{max} . There have been no attempts at development of B_{lim} for this stock. At present, the lack of an agreed catch and subsequently, an assessment, prevents further development of reference points.

Redfish in Div. 3M

Limit reference points can be derived from available YPR analysis, however recent changes in natural mortality and the uncertainty of its level in the long term prevent the use of such analysis to establish LRP's for this stock.

Roughead grenadier in SA2+3

The main reason for the lack of approved limit reference points for this stock is the absence of an approved quantitative assessment, and the available survey series are relatively short for such a long live species.

1) 4. Scientific Council perform a review of the Div. 3M cod MSE.

The working group recommends Scientific Council discuss the following HCR options for Div. 3M cod:

Starting points

 $F_{status \, quo}$

40% reduction [SC interpreted this as "...in catches, for 2015"]

An HCR which meets management objectives 1 and 2 within five years, and within ten years, with:

risk calculated for each year in the time series

risk calculated for the end of the periods (final year)

risk averaged over the periods

Scientific Council responded:

SC is not in the position to recommend any of the HCRs tested for the Div. 3M cod because the HCRs tested do not meet the established management objectives. SC reviewed the MSE procedure and noted that it is necessary to better document how the uncertainty enters into the model and proposed some improvements to the estimation of risk in the Performance Statistics (PS) and to introduce uncertainty for the biological parameters. SC recommends some changes for the starting points, time periods, levels of *F* target and number of scenarios to be tested in the continuing work on the Div. 3M cod MSE.

SC reviewed the 3M Cod MSE results and concluded that differences in the results come mainly from the assumed stock recruitment relationship and, to a much lesser extent, the assumed natural mortality (M) and the different F_{target} levels tested. The impact on the results of the assumed variability of the biological parameters for the projection period could be important. None of the tested HCR reached the established performance objectives in the 2016-2020 period but most of the scenarios met the performance objectives at the end of the 2021-2025 period. The main reasons for not achieving these objectives are the high initial F and catch levels combined with the 20% catch constraint. The results show that for both HCR it is very difficult to achieve the approved risk levels for different management objectives while maintaining stability in catches (catch constraint).

Following the recommendations of the FC-SC WG on Risk-Based Management Strategies (RBMS), SC performed a review of the Div. 3M cod MSE and recommended that it is necessary better document how the uncertainties enters into the model and proposed some improvements to estimate the risk of the Performance Statistics and the introduction of uncertainty in the biological parameters for future runs. SC proposed to estimate the "real" limits and targets for the different OMs based on the suggested Stock/Recruitment relationships to measure the risk to be below the true simulated B_{lim} and F_{lim} . SC also proposed including in the analysis the annual variability in the mean weights at age.

SC endorsed the FC SC RBMS WG recommendations to test different starting points levels as well as measures the management objectives 1 and 2 in a five and ten years periods with three different PS: by year, at the end of the periods and the mean of the periods.

Scientific Council recommends that the SC-FC WG-RBMS continue the MSE evaluation of HCRs for Div. 3M cod, incorporating the following:

- 1. Remove the 20% TAC constraint from the HCR and measure the TAC stability as a Performance Statistic.
- 2. To use the last approved assessment and management measures as starting point and make the projections for ten years.
- 3. Remove the Natural Mortality variable OM from the Div. 3M Cod MSE analyses based on the small impact of this OM in the final results compare with the fixed Natural Mortality OM.
- 4. To test only two F_{target} levels in the Model Based HCR (probabilities of 20% and 40% of exceeding F_{msy}) based on the NAFO PA framework, taking into account the small differences in F for the different probability levels of exceeding F_{msy} , to reduce the number of the scenarios to be tested to about a third.

From the Working Group on Risk-Based Management Strategies in 2014 (FC-SC Doc. 14/02).

5. The WG **recommends** SC comment on likely by-catch levels associated with the implementation of the proposed HCR for 3LN Redfish (Annex 7).

A preliminary working paper was reviewed and further analysis will be carried out in advance of the September meeting. All countries involved in the fishery were encouraged to attempt complimentary analysis of their bycatches.

XV. ADOPTION OF SCIENTIFIC COUNCIL REPORT

At its concluding session on 11 June 2015, the Council considered the draft report of this meeting, and adopted the report with the understanding that the Chair and the Secretariat will incorporate later the text insertions related to plenary sessions of 29 May-11 June 2015 and other modifications as discussed at plenary.

XVI. ADJOURNMENT

The Chair thanked the participants for their hard work and cooperation, noting particularly the efforts of the Designated Experts and the Standing Committee Chairs. The Chair thanked the Secretariat for their valuable support and St Mary's University for the excellent facilities. There being no other business the meeting was adjourned at 1400 hours on 11 June 2015.

APPENDIX I. REPORT OF THE STANDING COMMITTEE ON FISHERIES ENVIRONMENT (STACFEN)

Chair: Andrew Cogswell

Rapporteur: Gary Maillet

The Committee met at the Sobey School of Business (Unilever Lounge), Saint Mary's University, 903 Robie St., Halifax, NS, Canada, on June 1st, 2015, to consider environment-related topics and report on various matters referred to it by the Scientific Council. Representatives attended from Canada, Denmark (in respect of Greenland), Greenland, European Union (Germany (via WebEx), Portugal, and Spain), Russian Federation, USA and Japan.

Highlights of Climate and Environmental Conditions in the NAFO Convention Area for 2014

a) Meteorological and ice conditions

- The North Atlantic Oscillation index (NAO), a key indicator of climate conditions over the North Atlantic returned to a strongly positive phase in 2014 (anomaly of 11.5 mbars or 1.3 Standard Deviations (SD) above normal) resulting in strong arctic air outflow in the northwest Atlantic during the winter months and consequently lower than normal winter air temperatures.
- The annual mean air temperature at Nuuk Weather Station in West Greenland was -0.6°C in 2014, 0.8°C above the long term mean (1981-2010).
- During the winter convection season, surface air temperatures in the Labrador Sea were 1-3°C above normal but late winter was below normal.
- There was a significant decrease in winter air temperatures (-0.6 to -1.0 SD below normal) over much of the NL region compared to 2013.
- Annual air temperatures over Labrador (at Cartwright) were near normal and slightly above normal (0.4 SD) over Newfoundland (at St. John's).
- 2014 was ranked as the 15th warmest year (air temperature) for the 115 year time series for the Scotian Shelf and Gulf of Maine. With the exception of Boston (-0.3°C and 0.4 SD) all other sites experienced warmer annual temperatures than normal, from just slightly positive in Saint John (<0.1°C and <0.1 SD) to +1.2°C (+1.7 SD) at Sable Island.
- Air temperatures were cooler than average during the winter and spring (1981 2010) over the North-eastern United States (NEUS) continental shelf, with enhanced positive anomalies in summer and fall suggesting a larger seasonal range in 2014.
- Most of the Labrador Shelf experienced above normal ice concentrations during the winter months. The northern part of the Labrador Sea experienced ice concentrations ~25% below normal in January but ~25% above normal in March.
- Sea ice extent on the NL shelf increased substantially during the winter of 2014, with the first positive (higher than normal extent) anomaly observed in 16 years.
- There were 1546 icebergs detected south of 48°N on the Northern Grand Bank in 2014 (1.2 SD above normal), the 6th highest count since 1900.
- Ice coverage and volume on the Scotian Shelf in 2014 were slightly above the 1981 2010 average, unlike the preceding four years which had extremely low coverage and volume.

b) **Temperature and salinity conditions**

- The annual sea surface temperature (SST) anomalies for 2014 indicate positive anomalies in the Northwestern Atlantic around Greenland, with the highest values occurring northeast of Iceland and lowest values observed in the central area of the North Atlantic.
- Irminger Sea Water (ISW 75-200 m) at Cape Desolation station 3 was 6.27°C and 34.89, which was 0.55°C and -0.03 below the long-term mean, respectively. This continues the long term warming trend observed in ISW at Cape Desolation starting in 1983.
- North Atlantic Deep Water (NADW 2000 m) at Cape Desolation Station 3 also continues a warming trend with correspondingly more saline waters that began in the late 1990's.
- The temperature and salinity of water between 0 and 50 m depth at Fyllas Bank Station 4 (monitoring the variability of the fresh Polar Water component of the West Greenland current) was 0.74°C above and 0.22 P.S.U above the long-term mean (1981 2010) in the spring and 0.76°C and 0.42 above the long term mean in the fall.
- During the winter convection season, the sea surface temperature anomalies in the Labrador Sea showed a mixed sea surface temperature (SST) pattern, with both negative and positive anomalies.
- Triggered by winter time cooling, Labrador Sea convection in 2014 reached at least 1600 m and possibly as deep as 1800 m, significantly deeper than convective mixing observed in 2013.
- Considerable seasonal variability in SST was observed at Station 27, with a strong negative anomaly during the spring and strong positive anomalies observed from June to late November.
- Annual vertically averaged temperature at Station 27 off Southeastern NL was slightly below normal in 2014. This is a continuation of a trend in declining temperatures from the record high experienced in 2011 (+2.7 SD)
- Station 27 bottom temperatures were 0.6 SD (-0.2°C) below normal in 2014, a continuation of a trend of declining bottom temperatures from the record high experienced in 2011 (+3.6 SD) and the lowest since 1995.
- The area of the cold intermediate layer (CIL) water mass (<0°C) on the NL Shelf along standard sections during the spring, summer were above normal, the highest level since 1985 on the Ground Bank during the spring and the highest since 1991 off eastern Newfoundland during the summer. In fall, CIL area was only slightly above normal on the Grand Bank and approximately normal along the Bonavista and Southeast Grand Bank sections.
- Spring bottom temperatures in NAFO Div. 3P were ~1 SD above normal in 2014, similar to 2013 but less than the maximum experienced in 2012. Divs. 3LNO bottom temperatures were slightly below normal in 2014 (-0.1 SD), a continuation of a decline in bottom temperatures beginning after a high in 2011 (1.9 SD).
- Autumn bottom temperatures in 2J and 3K were slightly above normal by 0.7 and 0.3 SD in 2014. This is a continuation of a decline in bottom temperatures beginning after a high of 2.0 and 2.7 SD in 2011. The 2014 value for bottom temperature for 3LNO was not available.
- A composite climate index derived from 28 meteorological, ice and ocean temperature and salinity time series for the NL region show a declining trend since the peak in 2010. 2014 represents the 11th lowest composite climate index for the NL region in the last 65 years and the lowest since 1994.
- During 2014, temperatures along the Flemish Cap section were mostly below normal during all seasons but particularly during spring when upper layer values reached 1-2°C below normal. These anomalies penetrated to the bottom over the Cap with a striking cold anomaly persisting at depth over the Cap during the fall.
- A well-defined cold-intermediate layer (CIL) with a temperature < 3°C over the Flemish Cap was evident in the summer and fall of 2014.
- SST annual anomalies on the Scotian Shelf were positive during 2014, ranging from 0.5°C (+0.4 SD) in Cabot Strait to +1.8°C (+1.5 SD) on the Western Bank. This is a continuation of increasing temperature trends over the length of the records over the entire Scotian Shelf.
- The 2014 annual temperature anomaly at Prince 5 (0-90 m) was +0.7°C (+1.4 SD) and the salinity anomaly was +0.1 (+0.4 SD), slightly warmer and less saline than 2013. The partial

- The CIL volume on the Scotian Shelf in 2014 was 3300 km³, 1.9 SD less than the 1981 2010 mean. This was almost as small as the minimum value seen in 2012, the smallest volume in the 41 years of surveys.
- The climate index, a composite of 18 selected, normalized time series on the Scotian Shelf, averaged +1.6 SD, making 2014 the second warmest year in the last 45 years.
- Relative to historical values, regional ocean temperatures across the NEUS shelf were uniformly warmer and saltier during 2014. Of the seasons sampled, warming was most pronounced during late-summer/early-fall, with regional temperature anomalies reaching nearly 2°C all the way to the bottom. The large regional salinity anomalies observed in the Middle Atlantic Bight are reflective of a large swath of positive anomalies extending from the shelf edge toward shore between Cape Cod, MA and Cape Hatteras, NC.
- Extreme temperature and salinity anomalies observed over the NEUS during summer and fall of 2014 were likely caused by a procession of Gulf Stream warm core rings, whose interaction with the topography at the shelf break drove an incursion of Gulf Stream water onto the inner shelf between spring and fall of 2014.
- Winter mixed layers along the NEUS shelf during 2014 were four times as deep and 2°C colder than those observed in 2012.

c) Biological and chemical conditions

- pH in the central part of the Labrador Basin continues to show a sustained rate of decline (0.0032/year) since 1996 in the newly ventilated water masses of the central part of the Labrador Basin (150 500 m).
- Silicate concentrations in the newly ventilated layer of the central Labrador Basin (150 500 m) continue to decrease since 1991 (0.07 μ mol kg⁻¹ y⁻¹), following the same trend as has been observed over the rest of the North-western Atlantic.
- Winter conditions and deep convection in the Labrador Sea delayed the phytoplankton bloom by almost a month with cascading effects on the lower trophic levels, thus delaying and supressing the production of Calanus finmarchicus and other mezooplankton taxa, with all taxa exhibiting lower abundance than normal.
- Continuing a trend beginning in 2008, deeper nitrate inventories (>50 m) remain below average over the northern transects (Grand Bank and Labrador/NL shelf), approaching 4- 5 SD below normal in 2014.
- The chlorophyll a inventories inferred from the seasonal AZMP oceanographic surveys and fixed stations were variable throughout the Subareas in 2014 with below normal conditions over the northern transects (2J to 3LNO), generally above average in the Gulf of St. Lawrence, and near-normal throughout the Scotian Shelf.
- The magnitude (integral of chla biomass) and amplitude (peak intensity) of the spring bloom inferred from remote sensing was typically below normal across most of the northwest Atlantic in 2014 with 18/19 of 24 sub-regions showing negative anomalies respectively.
- The initiation and duration of the spring bloom was later on average and limited in 2014 with predominately positive (delayed) and negative (reduced) anomalies.
- The zooplankton abundance anomalies for a dominant small grazing copepod were generally positive over much of the survey transects and fixed stations in 2014 with the highest abundance levels observed over the Grand Bank (3LM) and Gulf of St. Lawrence.
- In contrast, the abundance for a dominant large grazing copepod was lower throughout the Subareas with the largest decline observed over the eastern Scotian Shelf.
- In general, the total number of copepod taxa increased from 2013 levels but, approached nearly 4 standard deviation units above normal at the fixed sampling station in the Gulf of St. Lawrence in 2014.
- The non-copepod taxa, characterized by carnivorous zooplankton, gelatinous invertebrates, and meroplankton, have increased substantially in recent years throughout the northeast Newfoundland Shelf and eastern Gulf of St. Lawrence, in some cases approaching 5-20 SD above normal.

1. Opening

The Chair opened the meeting by welcoming participants to this June 2015 Meeting of STACFEN.

The Committee adopted the agenda and discussed the work plan and noted the following documents would be reviewed: SCR Docs. 15/01, 02, 04, 05, 10, 11, 12, 13, 14, 15, 24, 25.

2. Appointment of Rapporteur

Gary Maillet (Canada) was appointed rapporteur.

3. Adoption of the Agenda

The provisional agenda was adopted with no further modifications.

4. Review of Recommendations in 2014

STACFEN **recommended** Secretariat support for one invited speaker to address emerging environmental issues and concerns for the NAFO Convention Area during the Annual June Meeting.

STATUS: An invited speaker was supported in 2015, discussing the incorporation of environmental variability in a fishery stock assessment. As well, there were 3 interdisciplinary presentations: the first by Dr. Pierre Pepin on preliminary results from a study of the delineation of ocean acidification and calcium carbonate saturation state of the Atlantic zone, and the other 2 presented by Dr. Aldo Solari on environmental forcing effects on Greenland halibut dynamics and the use of radio-isotopes in otolith analysis as an identifier of life history changes.

5. Invited Speaker

The Chair introduced this year's invited speaker Dr. Jae Choi.

The following is an abstract of Dr. Choi's presentation entitled "A case study in the incorporation of environmental variability in a fishery stock assessment: 4VWX snow crab (*Chionoecetes opilio*)"

There has been long-standing awareness and interest in incorporating the role of environmental and ecosystem variability to make stock assessments more precise. With increasing awareness of rapid climate (and ecosystem) change and their potential ramifications upon fishery status and viability, management discussions and decisions require guidance. The fishery stock assessment of NAFO Divs. 4VWX snow crab (Chionocetes oplio) attempts to incorporate this information in providing stock assessment advice to fishery managers and industry. The approaches adopted in this fishery are identified and the associated costs and benefits are highlighted.

6. Oceanography and Science Data (OSD) Report for 2014 (SCR Doc. 15/14)

Since 1975, Oceanographic Services (OS) (formerly ODS, ISDM and MEDS) has been the regional environmental data centre for ICNAF and subsequently NAFO and as such is required to provide an inventory of all environmental data collected annually by contracting countries of NAFO within the convention area. A review of the OSD Report for 2014 was provided in **SCR Doc. 15/14.** OS is the Regional Environmental Data Center for NAFO and is required to provide an annual inventory of environmental data collected in the NAFO regulatory area to the NAFO Standing Committee on Fisheries Environment (STACFEN). In order for OSD to carry out its responsibility of reporting to the Scientific Council, the Designated National Representatives are requested to provide OSD with all marine environmental data collected in the Northwest Atlantic for the preceding years. Provision of a meaningful report to the Council for its meeting in June required the submission to OS of a completed oceanographic inventory form for data collected in 2014, and oceanographic data pertinent to the NAFO area, for all stations occupied in the year prior to 2014. The data of highest priority are those from the standard sections and stations. Inventories and maps of physical oceanographic observations such as ocean profiles, surface thermosalinographs, drifting buoys, currents, waves, tides and water level measurements for the calendar year 2014 are included. This report also provides an update on other OS activities during 2014. Data that have been formatted and archived at OS are available to all NAFO member states upon request. Requests can be made by telephone (613) 990-6065, by e-mail to isdmgdsi@dfo-mpo.gc.ca, by completing an on-line order form on the OS web site at http://www.meds-sdmm.dfo-

<u>mpo.gc.ca/isdm-gdsi/request-commande/form-eng.asp</u> or by writing to Oceanographic Services (OS), Fisheries and Oceans Canada, 12th Floor, 200 Kent St., Ottawa, Ont. Canada K1A 0E6.

95

Highlights of Oceanographic Services (OS formerly ODS, ISDM and MEDS) Report for 2014:

The following is the inventory of oceanographic data obtained by ISDM during 2014:

Data Type	Platform Type	Counts/Duration	
	autonomous platforms	18783* profiles from 133 platforms	
Oceanographic profiles	ship	2271 profiles (1508 +763* real-time) from 23 ships	
	moored ADCP	3 sites, 290 days each	
	ship (thermosalinograph)	11316* obs. from 2 ships	
	drifting buoys	368514* obs. from 161 buoys	
	moored buoys temp/waves	53520* obs. from 9 buoys	
Surface/near-surface observations	moored buoys temp/salt	114280* obs. from 16 buoys	
	fixed platforms	84591* obs. from 5 platforms	
	water level gauges	21 sites, average of 12 months each	

*Data formatted for real-time transmission

0

The following were data observed prior to 2014 in NAFO Convention Area and acquired in 2014:

Data Type	Platform Type	Counts/Duration
	ship	7694 profiles from 31 ships
Oceanographic profiles	moored ADCP	3 sites, 70 days each
	Moored thermistor	210 time series at 87 sites, average of 181 days each
0		

7. Results of Ocean Climate and Physical, Biological and Chemical Oceanographic Studies in the NAFO Convention Area

A key indicator of ocean climate conditions, the North Atlantic Oscillation (NAO) index, returned to a strongly positive phase in 2014 which contributed to strong arctic air outflow in the northwest Atlantic during the winter months and consequently lower than normal winter air temperatures at most locations. As a result, sea ice extent increased substantially during the winter of 2014, with the first positive anomaly (higher-than-normal extent) observed in 16 years on the NL Shelf.

Subareas 0 and 1. Reviews of meteorological, sea ice and hydrographic conditions in West Greenland in 2014 were presented in **SCR Docs. 15/01 and 15/02**.

Despite a strongly positive NAO phase in 2014, the annual mean air temperature at the Nuuk weather station was -0.6°C, 0.8°C above the long-term mean (1981-2010). The annual sea surface temperature (NOAA OI SST) anomalies for 2014 indicate positive anomalies of the SST in the Northwestern Atlantic around Greenland, with the highest values occurring northeast of Iceland and lowest values observed in the central area of the North Atlantic. The time series of June/July near-surface temperatures on Fyllas Bank (0-50 m), while lower than in 2013, were still 0.76°C higher than the long-term mean (1981-2010), and corresponding salinity values continued their positive trend (starting around 1970) and were 0.22 above the long-term

mean. The temperature and salinity of the Irminger Sea Water (ISW) component of the West Greenland Current at Cape Desolation Station 3 was 5.41° C and 34.89, which was 0.76° C and 0.01 above the long-term mean (1992-2010), respectively. Pure ISW did not appear to be present on the west coast off Greenland in June/July 2014, but diluted ISW could be followed from the Cape Farwell section (60° N) to the Sisimiut section in the north (67° N). North of the Sisimiut section, this water becomes increasingly colder and fresher with distance. By Upernavik ($\sim73^{\circ}$ N), the core properties of this water were 3.17° C and 34.57 for potential temperature and salinity respectively.

In October/November 2014, the hydrographic conditions of two oceanographic NAFO/ICES sections, which span across the western shelf and continental slope of Greenland near Cape Desolation and Fyllas Bank were monitored. The temperature and salinity of the ISW component of the West Greenland Current at Cape Desolation Station 3 was 6.27°C and 34.89, which was 0.55°C above and -0.03 below the long-term mean (1983-2010), respectively. The properties of the North Atlantic Deep Water in the deep boundary current west of Greenland are monitored at 2000 m depth at Cape Desolation Station 3. After slightly above-average temperature and salinity observed in 2013, the temperature increased in 2014 and was 0.17°C above the long-term mean. The water properties between 0 and 50 m depth at Fyllas Bank Station 4 are used to monitor the variability of the fresh Polar Water component of the West Greenland current. In 2014, the temperature of this water mass was 0.74°C - 0.76°C above its long-term mean and salinity was 0.22 - 0.42 above its long-term mean.

Subareas 1 and 2. A review of physical, chemical and biological oceanographic conditions over the Labrador Sea in 2014 was presented in **SCR Doc. 15/15**.

The NCEP reanalysis of surface air temperature indicated above normal temperature conditions with an anomaly ranging between $1 - 3^{\circ}$ C in the Labrador Sea during the winter period; ~ 1° C below normal for the most of Labrador Sea during spring; $\sim 1^{\circ}$ C above normal for the summer period; and with an anomaly of 0 – 2°C during the fall. Sea surface temperature (SST) anomalies in the Labrador Sea mostly followed the patterns observed in the air temperature except in winter when there was a mixed SST pattern, with negative and positive anomalies in the Labrador Sea, while for other seasons, positive anomalies were the dominant feature as for the air temperature. Most of the Labrador Shelf ice concentration was above normal in the winter months of 2014 (reference period: 1979-2000). But in the northern part of the Labrador Sea, the sea ice concentration was $\sim 25\%$ below normal in January, and interestingly, the same region had $\sim 25\%$ above the normal ice concentration in March. Wintertime convection in 2014 reached 1800 m, which is significantly deeper than the 1000 m seen in the previous year. The deeper part of the intermediate layer (1800-2500 m) of the central Labrador Sea has been gradually warming since the mid-1990s. DIC and pH are following their usual inverted pattern yielding a sustained decline rate in pH of 0.0032 per year since 1996. Silicate concentration in the newly ventilated layer is also decreasing, following the same trend as has been observed in the rest of the North-western Atlantic. Winter conditions and deep convection delayed the phytoplankton bloom by almost a month with a cascading effect on the lower trophic levels thus delaying production by Calanus finmarchicus and most of the mezooplankton taxa with all taxa exhibiting lower abundance than normal. In May, the *C. finmarchicus* community was still exhibiting the characteristic of a population slowly emerging from their overwintering condition.

Subareas 2 and 3. A description of environmental information collected in the Newfoundland and Labrador (NL) Region during 2014 was presented in **SCR Doc. 15/11 and SCS Doc. 15-08**.

The North Atlantic Oscillation index, a key indicator of climate conditions on the Newfoundland and Labrador Shelf, returned to a strong positive phase in 2014 at 1.3 SD above normal. This resulted in increased Arctic air outflow during the winter (over the previous year) causing a significant decrease in winter air temperatures (-0.6 to -1.0 SD below normal) over much of the NL region. As a result, the sea ice extent on the NL Shelf returned to slightly above normal conditions (0.4 SD during winter), the first positive anomaly in 16 years. As well, 1546 icebergs were detected south of 48°N on the Northern Grand Bank, compared to only 13 in 2013, 1.2 SD above the 1981-2010 mean of 767. Despite overall regional cooling in 2014, annual air temperatures were near normal over Labrador (at Cartwright) and slightly above normal by 0.4 SD over Newfoundland (at St. John's).

Despite cool winter condition in 2014, annual sea-surface temperatures (SST) remained above normal in most areas across the Newfoundland and Labrador Shelf; however, values have declined from record-highs

observed in 2012. The annual bottom (176 m) water temperature at the inshore monitoring station (Station 27) was below normal in 2014 by -0.6 SD, a significant decrease from the record high in 2011. The coldintermediate layer (CIL; volume of < 0° C) in 2014 was at its highest level since 1985 on the Grand Bank during the spring and the highest since 1991 off eastern Newfoundland during the summer. Spring bottom temperatures in 3Ps remained above normal by about +0.5 SD but were slightly below normal on the Grand Banks by -0.3 SD. Fall bottom temperatures in 2J and 3K decreased from 2 and 2.7 SD above normal in 2011 to 0.7 and 0.3 above normal in 2014, respectively, a significant decrease in the past 3 years. As a result, the area of bottom habitat covered by water <2°C increased to near-normal values in 2014 during both spring and fall. A standardized climate index derived from 28 meteorological, ice and ocean temperature and salinity time series declined for the 3rd consecutive year, reaching the 11th lowest in 65 years and the lowest since 1994.

97

A description of physical oceanographic condition on the Flemish Cap during 2014 was presented in **SCR Doc. 15/13.**

Oceanographic observations from seasonal surveys in Div. 3M during 2014 are presented referenced to their long-term (1981-2010) means. An analysis of infrared satellite imagery around the Flemish Cap indicates that annual sea-surface temperatures (SST) decreased to about -0.6°C below normal in 2014, while water column temperatures decreased to -0.8°C, -0.4°C and -0.7°C below normal at 10, 50 and 100 m depth, respectively. The results from seasonal surveys along the standard Flemish Cap section show the development of a welldefined cold-intermediate layer (CIL) with T<3°C over the Cap during the summer and fall of 2014. Temperatures along the section were predominately below normal during spring, summer and fall but particularly during the spring survey when upper layer values reached between 1°C - 2°C below normal. The cold water penetrated to the bottom directly over the Cap with a cold anomaly persisting at depth over the Cap during the fall survey. The corresponding salinity cross-sections show relatively fresh upper layer shelf water with some areas <33.5, corresponding to generally fresher than normal conditions in most areas of the water column over the Cap. The spatial extent and average thickness of the CIL observed in 2014 was close to that observed during the cold period of early-mid 1990s. In 2014, bottom temperatures ranged from 2.7°C -3°C over the centre of the Cap which was up to -0.6°C below the long-term average. Nonetheless, it appears that the below normal temperatures only impacted the bottom area over the shallow portions of the Cap during the summer but expanded deeper into the water column by late fall. In general, there was a significant decrease in bottom temperatures in 2014 compared to the previous year (by $>1^{\circ}$ C) thus reversing the decade long warm trend in the waters of the Flemish Cap.

An investigation of the biological and chemical oceanographic conditions in subareas 2 to 5 in 2014 was presented in **SCR Doc. 15/10** and **SCS Doc. 15-08**.

Biological and chemical variables collected in 2014 from coastal high frequency monitoring stations, semiannual oceanographic transects, and ships of opportunity ranging from the Labrador-Newfoundland and Grand Banks Shelf (Subareas 2 and 3), extending west into the Gulf of St. Lawrence (Subarea 4) and further south along the Scotian Shelf and the Bay of Fundy (Subarea 4) and into the Gulf of Maine (Subarea 5) are presented and referenced to previous information from earlier periods when available. We review the interannual variations in inventories of nitrate, chlorophyll a and indices of the spring bloom inferred from satellite ocean colour imagery, as well as the abundance of major functional taxa of zooplankton collected as part of the 2014 Atlantic Zone Monitoring Program (AZMP) and Continuous Plankton Recorder (CPR) Survey to 2013. In general, nitrate inventories in the upper (0.50m) water-column were near normal (within ± 0.5 standard deviation (SD) units of the 1999-2010 climatology) throughout the northwest Atlantic in 2014. The deeper (50-150m) nitrate inventories continue to remain well below normal with levels approaching 4-5 SD units lower along the northern transects, an ongoing decline that began in 2008. In contrast, deep nitrate levels have recovered from lower levels observed in 2010-2011 across the Gulf of St. Lawrence and nearnormal along the Scotian Shelf in recent years (2012-2014). The chlorophyll *a* inventories inferred from the seasonal AZMP oceanographic surveys and fixed stations were variable throughout the Subareas, with below normal conditions over the northern transects (2] to 3LNO), generally above average in the Gulf of St. Lawrence, and near-normal throughout the Scotian Shelf. Satellite ocean colour imagery indicated lower biomass and weaker spring blooms over the NW Atlantic in 2014. The initiation and duration of the spring bloom was later on average and limited in 2014 with predominately positive (delayed) and negative (reduced) anomalies respectively. Peak timing of the spring bloom varied across the different Subarea's with earlier production cycles in the northern regions while delayed on the Newfoundland and Scotian Shelf in 2014. The zooplankton abundance anomalies for a dominant small grazing copepod were generally positive over many of the survey transects and fixed stations with the highest abundance levels observed over the Grand Bank (3LM) and Gulf of St. Lawrence. In contrast, the abundance for a dominant large grazing copepod was lower throughout the Subareas with the largest decline observed over the eastern Scotian Shelf in 2014. In general, the total number of copepod taxa increased from 2013 levels throughout the northwest Atlantic in 2014. The non-copepod taxa, characterized by carnivorous zooplankton, gelatinous invertebrates, and meroplankton, have increased substantially in recent years throughout the northeast Newfoundland Shelf and eastern Gulf of St. Lawrence.

Subarea 4. A description of environmental information collected on the Scotian Shelf and in the eastern Gulf of Maine and adjacent offshore areas during 2014 was presented in **SCR Doc. 15/05**.

A review of the 2014 physical oceanographic conditions on the Scotian Shelf and in the eastern Gulf of Maine and adjacent offshore areas indicates that above normal conditions prevailed. The climate index, a composite of 18 selected, normalized time series, averaged +1.6 standard deviations (SD), marking 2014 as the second warmest year in the last 45 years. The anomalies did not show a strong spatial variation. Bottom temperatures were above normal with anomalies for Divs. 4Vn, 4Vs, 4W, 4X of +1.2°C (+2.8 SD), +1.1°C (+1.6 SD), +2.0°C (+2.6 SD), and +1.7°C (+2.4 SD) respectively. Compared to 2012, the year where record or near record bottom temperatures were observed, bottom temperatures were different by +0.7°C, -0.2°C, +0.2°C and -0.4°C in Divs. 4Vn, 4Vs, 4W and 4X, respectively.

Subareas 5 and 6. A description of environmental information collected on the Northeast United States Continental Shelf during 2014 was presented in **SCR Doc. 15/04**.

The analysis utilizes hydrographic observations collected by the operational oceanography programs of NOAA Fisheries Service, Northeast Fisheries Science Center (NEFSC), which represents the most comprehensive consistently sampled ongoing environmental record within the region. Overall, 2014 was characterized by continued warming throughout the water column, an increase in the seasonal range of temperature and generally more saline conditions across the region. Deep (slope) waters entering the Gulf of Maine were warmer and saltier than average and their temperature and salinity suggest a subtropical source. Mixed layers in the western Gulf of Maine were anomalously deep during the winter of 2014, presumably a consequence of anomalously cold air temperatures that persisted over the northeastern United States during winter. The vigorous mixing led to the formation of an anomalously thick layer of cold intermediate water in the following spring. Finally, observations reveal a significant intrusion of Gulf Stream water in the Middle Atlantic Bight during late summer. The intrusion encompassed the width of the shelf, leading to profound changes in the water mass distributions. Such episodic events have the potential to cause significant changes in the ecosystem, including changes in nutrient loading on the shelf, the seasonal elimination of critical habitats such as the cold pool and shelf-slope front, disruption of seasonal migration cues, and an increase in the concentration of offshore larval fish on the shelf.

8. Interdisciplinary Studies

An important role of STACFEN, in addition to providing climate and environmental summaries for the NAFO Convention Area, is to determine the response of fish and invertebrate stocks to the changes in the physical and biological oceanographic environment. It is felt that a greater emphasis should be placed on these activities within STACFEN and the committee recommends that further studies be directed toward integration of environmental information with changes in the distribution and abundance of resource populations.

The following interdisciplinary studies were presented at the June 2015 Meeting along with relevant abstracts:

Preliminary Results of an ACCASP Funded Study of the Delineation of Ocean Acidification and Calcium Carbonate Saturation State of the Atlantic Zone. Authors: P. Pepin, K. Azetsu-Scott, M. Starr, S. Punshon and G. Maillet. Presented in SCR Doc. 15/12.

Ocean acidification, a consequence of rising anthropogenic CO_2 emissions, is poised to change marine ecosystems profoundly by increasing dissolved CO_2 and decreasing ocean pH, carbonate ion concentration,

and calcium carbonate mineral saturation state (CaCO₃) worldwide. The Northwest Atlantic is one of the most important sites for sequestering atmospheric CO₂ and contains the largest inventory of anthropogenic CO₂ in the world. Waters from the Labrador Sea impact continental shelves throughout the Atlantic Zone. In the St. Lawrence Estuary, acidification is closely related to hypoxia, caused by the multi-decadal changes in water mass composition combined with *in-situ* respiration during the slow estuarine transport of deep waters towards the heads of the channels. The Atlantic Basin Impacts and Vulnerability Assessment identified the lack of information on the state of calcium carbonate mineral saturation and ocean acidity for the continental shelves as an important limitation in evaluating the potential risk of anticipated increase in ocean acidification to shellfish (e.g. mussels, scallops, clams) and invertebrate (e.g. crabs, shrimp, lobsters) fisheries, as well as organisms that are critical to maintaining ecosystem function (e.g. corals, sea pens, sea urchins and various zooplankton) (Shackell *et al.* 2014).

99

In this study, we aimed to establish the baseline conditions of the saturation state of seawater and pH to assess the potential of future changes on the Canadian continental shelves in the northwest Atlantic, based on a series of oceanographic surveys of the Scotian Shelf, Gulf of St. Lawrence and Newfoundland and Labrador Shelves during the fall of 2014. The *in situ* pH_{total} ranged from 7.87 to 8.33 on the Newfoundland Shelf, 7.56 to 8.09 in the Gulf of St. Lawrence and 7.80 to 8.11 on the Scotian Shelf. On both the Newfoundland and Scotian shelves pH_{total} demonstrated a general positive relationship with temperature but there was differing degrees of variability around the relationship in each region. However, the pattern of variation in pH_{total} was more complex in the Gulf of St. Lawrence and the causes are still being investigated. Aragonite saturation states (Ω_{arg}) at the bottom (5-10 m from bottom down to 1000 m in offshore areas) demonstrate a considerable degree of spatial variation, with most of the Gulf of St. Lawrence and Laurentian Channel being below saturation ($\Omega_{arg} < 1$) throughout most of the region. Low (Ω_{arg} range 1-1.1) and relatively low (Ω_{arg} range 1.1-1.2) saturation states are present in the eastern Scotian Shelf as well as on portions of the northern Grand Banks. Samples with low aragonite saturation states, either near the bottom or in the water column) tended to be associated with water masses in the cold intermediate layer and/or areas with low oxygen concentrations. Further analyses will be carried out to determine whether there are significant regional differences in carbonate chemistry that would reflect contrasting influences of freshwater input, biological production, and water mass characteristics and residence times.

On Greenland Halibut Dynamics: Update on Environmental Forcing. Author: A. Solari. Presented in SCR Doc. 15/24

Currently, we develop a "top down systems approach" on Greenland Halibut (WGH) dynamics in order both to understand and describe the causal mechanisms of the spatio-temporal evolution of the stock, link the offshore and in-shore systems and propose fishing mortality ranges (F_i) adapted to life history aspects (derived from survey data and otolith biochemistry analysis), based upon variable population reference points (K_{i} , r_{i} , $M_{\rm i}$), environmental and multi-species interactions, by-catches from the shrimp fishery and estimated short term (\approx 6 years) trends thereof. Numerical, spatial and geometric system approaches for management proposals are in focus. Description of the systems are to be carried out through a matrix of GAMs (difference delayed equations) and polygon based on overlappings between densities and environmental iso-lines (aimed to managers). Sustainable harvesting strategies and conservation are the core of this line of work. There are several highlights from our results (April, 2015) which are both useful for development of models for sustainable spatio-temporal harvesting strategies: (i) Both linear and non-linear analysis showed that the *GH* stock has been underestimated/underexploited (during periods of higher abundances) and –what is most important- overestimated/overfished (during periods of lower abundances, when the stock is most vulnerable): this was due to the lack of analysis and an appropriate operational model, basing the assessment in series of mean values and omitting the variability in the data, lags and memories, minima and maxima (typical features for dynamical systems and population processes); (ii) Age 1 and abundance lagged 6 years

(1997-2011) may be related (p<.05) to (*a*) the variability of the SST in the area of the early life drift (mixing layer) and (*b*) recruitment and the fishable stock can be estimated from age class 1 (lagged 5 years); (*iii*) Abundance and CPUE were found to follow cycles at two levels of numbers and (*iv*) the relationships appeared to respond mainly to trends in temperature minima. A priori estimations of abundance as the inverse of the SST variation were validated for years 2012-2014, as well. Further details can be found in *Solari et al.* (2013, 2014, 2015).

Otolith Data Analysis: an ID to Life History Changes. Author: A. Solari. Presented in SCR Doc. 15/25 Authors: Solari, A., S. Rodríguez, R. Nygaard, S. Jeremiasen, J. Sethsen (2015).

The task is part (a sub-system) of a "top-down" system dynamics modelling (described by a non-linear GAM) on *Greenland Halibut* (GH) based on both variable population parameters (carrying capacity, K_i ; intrinsic rate of increase, r_i and natural mortality, M_i) and responses to the combined effects from both the environmental forcing and past fishing mortality. The main goal of this work is to produce a framework for both sustainability and conservation. The (laser ablation, spectrometrical) analysis of trace element series may allow for the inference of life history and environmental factors which affect the spatio-temporal evolution of the population: stepwise recruitment from age class 0-1, age at recruitment to the population, timings, feeding and habitat/depth changes and speed of growth, among others. In the first stage of this task, we attempted to estimate the age (without the need for isotope marked otoliths) and recruitment process out the series from the trace elements *Magnesium* (Mg, a proxy for feeding, probably biased by predation on shrimps) and Barium (Ba, a proxy for salinity) series (N=2059). To comply with both the Central Limit Theorem and conditions for statistical normality, we sampled 39 out of 144 otolith series and showed what we considered a "typical" example of an adult, large individual (a 94 cm, female, captured within the Davis Strait area at 1189 mts of depth). We worked on the raw, log transformed and standardized data. Also, we assumed that there would be (i) periodic peaks in Mg accumulation and (ii) we could infere the timing for the recruitment process, age and different life history aspects from splitting up the series using smoothers (simple regressions, cubic splines, locally weighted scatterplot smoothings (LOWESS) and B-splines) and R programming to determine maxima, minima, zero slopes, inflection points, spectrum and frequencies of processes from the multi-resolution decomposition (MRD, a wavelet analysis) of the data. By exclusion of frequencies, we could determine (D6 processes in the wavelet analysis): (i) yearly processes in Mg accumulation and age (24 years old); (ii) five discrete life history stages (2 for pre-recruits aged 0-6 and 3 for adults aged 7-12, 13-20 and 21-24 years); (iii) age-at-recruitment to the population (during the 6th year) and several migration patterns linked thereby. The knowledge acquired by this method may be translated to major improvements both in modelling, management and sustainable (short term, six years) exploitation strategies. However, there are processes and patterns of higher resolution in the signals which remain to be investigated.

While not specifically designated as an "Interdisciplinary Study" during the meeting proceedings, following the overview of the "Physical Oceanographic Conditions on the Scotian Shelf and in the eastern Gulf of Maine" Dr. Dave Hebert provided an overview of recent activities pertaining to:

The 'Overturning in the Subpolar North Atlantic Program' (OSNAP) within the NAFO Convention Area:

OSNAP is an international program (USA, UK, Germany, Netherlands, France, Canada and China) designed to provide a continuous record of the full-water column, trans-basin fluxes of heat, mass and freshwater in the subpolar North Atlantic. The OSNAP observing system consists of two legs: one extending from southern Labrador to the southwestern tip of Greenland across the mouth of the Labrador Sea (OSNAP West), and the second from the southeastern tip of Greenland to Scotland (OSNAP East). The observing system also includes subsurface floats (OSNAP Floats) in order to trace the pathways of overflow waters in the basin and to assess the connectivity of currents crossing the OSNAP line.

The initial deployment of the observing system was carried out in the summer of 2014. The Canadian contribution to OSNAP includes moorings on the Labrador Shelf and shelf break in the vicinity of Belle Isle Bank, which is referred to as the 53N Line. The mooring array at 53N is a joint collaboration between Germany, Canada and the USA. The Labrador Sea eastern boundary array was deployed by the USA in August 2014 in the area of Cape Farewell, Greenland. The majority of the OSNAP moorings will be recovered and redeployed in 2016 with the program presently funded through 2018.

9. An Update of the On-Line Annual Ocean Climate and Environmental Status Summary for the NAFO Convention Area

In 2003 STACFEN began production of an annual climate status report to describe environmental conditions during the previous year. This web-based annual summary for the NAFO area includes an overview that summarizes the overall general climate changes for the previous year and a regional overview that provided climate indices from each of the Subareas. The climate summary is updated by the NAFO Secretariat on an annual basis with contributions from each contracting country. Information for 2014 will be made available from Subarea 1, West Greenland , Subareas 2-3, Grand Banks and Labrador Sea / Shelf , Subareas 4-5, Scotian Shelf and Gulf of Maine , and Subareas 5-6, Georges Bank and Gulf of Maine.

10. The Formulation of Recommendations Based on Environmental Conditions

STACFEN **recommends** consideration of support for one invited speaker to address emerging issues and concerns for the NAFO Convention Area during the 2016 STACFEN Meeting.

STACFEN **recommends** that a sub-committee of STACFEN members be formed to discuss and draft a plan towards the reconfiguration and/or amalgamation of STACFEN and WGESA to be presented at the 2016 STACFEN Meeting.

STACFEN **recommends** that a sub-committee of STACFEN members be formed to discuss the current state of Fisheries and Oceans Canada (DFO) Oceanographic Services (formerly ISDM and MEDS) data management responsibilities to NAFO and related mechanisms for the reporting of oceanographic data by member states and the subsequent means of accessing these data. It is recommended that the findings of these discussions be tabled at the 2016 STACFEN meeting and should represent a reasonable "road map" for data providers, data users, data managers and the NAFO Secretariat, given current requirements and in respect of the current human resource limitations to manage these requirements.

11. National Representatives

Currently, the National Representatives for hydrographic data submissions are: E. Valdes (Cuba), S. Demargerie (Canada), E. Buch (Denmark), <u>Vacant</u> (France), F. Nast (Germany), <u>Vacant</u> (Japan), H. Sagen (Norway), J. Janusz (Poland), <u>Vacant</u> (Portugal), M. J. Garcia (Spain), L. J. Rickards (United Kingdom), and K. J. Schnebele (USA; retired; temporary USA contact P, Fratantoni). B.F. Prischepa from Russia was replaced by K.V. Drevetniak.

The Secretariat will contact the countries where there are currently no National Representatives in order to fill these positions.

12. Other Matters

It was noted that an ongoing issue carried over from previous STACFEN meetings, is the relative ability of the Standing Council to fulfil one of its mandates that "STACFEN shall: provide reviews of environmental conditions and advise the Scientific Council on the effects of the environment on fish stocks and fisheries in the Convention Area". While there are significant hurdles (e.g., meeting timing, slightly differing mandates, etc...) there is a continued interest from NAFO SC to better integrate the activities of WGESA and STACFEN. In addition, there is also a continued interest to better utilize environmental data in single stock assessments. In response, a sub-committee was struck to manage these interests by initially drafting a "road-map" document with the ultimate goal of enhancing STACFEN's ability to facilitate FC/SC requests, better integrate oceanographic data into single species stock assessments and reduce redundancy by working with WGESA and/or merging overlapping activities. It is proposed that the results of this sub-committee can be used to create a draft document of this group's findings to be presented at the 2016 STACFEN meeting.

Management of NAFO Oceanographic data has become increasingly complex in recent years. With an ever increasing volume of data being submitted from automated and traditional systems to Fisheries and Oceans Canada - Oceanographic Services (OS), a corresponding decline in the financial and human resources for managing these data and a myriad of international databases for submitting/accessing similar data; there is currently a requirement to create a sub-committee to examine NAFO expectations for managing and accessing these data, the ability and willingness of DFO OS to continue to compile, manage, store and serve these data, and whether some of these efforts are duplicated by other international efforts. It is proposed that

Finally, Dr. Dave Hebert and Eugene Colbourne were consulted concerning the partial merger of reporting on physical oceanographic conditions for the Newfoundland and Labrador Shelves (subareas 2 & 3) and the Scotian Shelf (subarea 4) in advance of the 2016 STACFEN meeting. In the short-term it was agreed that Dr. Hebert would continue to prepare the SRC document summarizing physical oceanographic conditions in subarea 4, but that the presentation of the results would be combined with those for subareas 2 and 3 on the NL shelf at the 2016 STACFEN meeting.

13. Adjournment

Upon completing the agenda, the Chair thanked the STACFEN members for their excellent contributions, the Secretariat and the rapporteur for their support and contributions. Special thanks were again given to the invited speaker Dr. Jae Choi (Bedford Institute of Oceanography, Dartmouth, NS, Canada), and contributions to the interdisciplinary session by Dr. Pierre Pepin (Northwest Atlantic Fisheries Centre, St. John's, NL, Canada) and Dr. Aldo Solari (Greenland Institute of Natural Resources, Nuuk, Greenland).

The meeting was adjourned at 16:30 hours. on 1 June 2015.

APPENDIX II. REPORT OF THE STANDING COMMITTEE ON PUBLICATIONS (STACPUB)

103

Chair: Margaret Treble

Rapporteur: Alexis Pacey

The Committee met at the Sobey School of Business at St. Mary's University, 903 Robie St. Halifax, NS, Canada, on the 29 May and 11 June 2015, to consider publication-related topics and report on various matters referred to it by the Scientific Council. Representatives attended from Canada, Denmark (in respect of Greenland), European Union (France, Germany, Portugal and Spain), Norway, Russian Federation, Japan and the United States of America. The Scientific Council Coordinator was in attendance as were other members of the Secretariat staff.

1. Opening

The Chair opened the meeting at 10:00 a.m. by welcoming the participants.

2. Appointment of Rapporteur

Alexis Pacey (NAFO Secretariat) was appointed rapporteur.

3. Adoption of Agenda

The Agenda as given in the Provisional Agenda distributed prior to the meeting was adopted with the addition of items 6a) Review of JNAFS instructions for authors (manuscript preparation).

4. Review of Recommendations in 2014

STACPUB **recommended** that in order for authors to receive an SCR number they must submit a Title, Author and Abstract or Description of the document.

STATUS: This has been implemented.

STACPUB **recommended** that the Coral and Sponge Guides be updated to include the additional VME species that are listed in the CEM.

STATUS: In progress. See Review of Publications 5.vi) for an update on the VME guides.

STACPUB **recommended** that an excerpt from the Scientific Council meeting report that contains the advice and answers to the Fisheries Commission and coastal States requests be prepared and placed in a prominent place on the public website for easy accessibility.

STATUS: This is now available on the Science tab on the NAFO website. A direct link to Scientific Advice is found at the top of the Science webpage.

STACPUB **recommended** that the Secretariat work on providing direct links to key pages of the NAFO website and continue to provide easier access to documents and other information. STACPUB asked that these tasks be given a high priority by the Secretariat.

STATUS: The homepage of the NAFO website underwent some changes to improve access to documents and information. The homepage includes direct links to the main tabs of the website, a 'What's New' section was added, more visual images that have direct links to key areas, and a search button is now fully functional on the Publications tab. The search function is found on the left vertical menu. It searches for NAFO and ICNAF documents only.

Preliminary planning has started within the Secretariat to replace the framesets with a content management system (CMS). Considering the scale of the project and the resources available, this initiative will take considerable time, but still remains a priority.

STACPUB **recommended** that the NAFO Secretariat investigate options to promote the Journal using social media.

STATUS: This has been implemented. A Facebook share link is available at the top of each article.

STACPUB **recommended** that the NAFO Secretariat improve the visibility of the Journal by placing a prominent link directly on the NAFO websites homepage.

STATUS: This has been implemented.

5. Review of Publications

a) Journal of Northwest Atlantic Fishery Science (JNAFS)

Volume 46, Regular issue, was printed in December 2014 and mailed out in Jan. 2014. It was 45 pages and 140 copies were made. 20 CDs were made. A total of four articles were published. This year the printed copy was saddle-stitched.

Volume 47, Regular issue, has a total of seven papers that have been submitted for publication. One has been published (online); one is in production; five remaining are in the review process.

b) NAFO Scientific Council Studies

No Scientific Council Studies were published in 2014.

c) NAFO Scientific Council Reports

The NAFO Scientific Council Reports 2014 (Redbook) volume (421 pages) was produced in January 2015. A limited number of Reports have been printed and coil-bound as per the STACPUB recommendation from 2013. (Approx. 30 copies).

d) Meeting Documentation CD

STACPUB was informed that approximately 10 copies of the Meeting Documentation CD 2014 were produced. The CD contains:

- GC/FC Proceedings 13-14
- GC/FC Reports Sep 14
- SC Reports 2014
- NAFO Convention
- NCEM 2015
- Rules of Procedure
- Annual Report 2014

These reports and documents were also available on memory sticks as an alternative to a CD.

e) ASFA

Most science publications and documents have been submitted to ASFA as of May 30, 2015. This includes *The Journal of the Northwest Atlantic Fisheries*, SC Reports, and SC Research Documents for 2014. Any documents not yet submitted will be uploaded to ASFA once they are published online.

The NAFO Secretariat plans to co-host with Dalhousie University, Environmental Use and Influence, the ASFA Board Meeting being held in Halifax, 5-9 October, 2015.

f) VME Guides - New Coral and Sponge Guide 2015

STACPUB was informed that the SC Working Group on Ecosystem Science and Assessment (WGESA) discussed updating the existing NAFO coral and sponge identification guides (Kenchington *et al.* 2009, Best *et al.* 2010) to include the new VME indicator taxa (Murillo *et al.* 2011). WGESA decided that a second edition of the guide should be produced with the support of the NAFO Secretariat. The second edition should include all of the VME taxa, including the new taxa which are not in the current guides (i.e., erect bryozoans, stalked crinoids, large sea squirts and tube dwelling anemones). This would result in one book rather than 3 and would allow for updating of the corals and sponges at the same time as the new VME taxa.

The new book is currently in progress. Some discussion needs to take place to determine how the book will be sectioned. The new format will be in a poly binder with water resistant paper, as before, and there will be tabs to separate the different sections of taxa. This should be resolved soon so that production can take place

and the new book be made available for the NAFO Annual Meeting, which takes place between 21-25 September, 2015.

STACPUB **recommends** that the Secretariat contact WGESA for further instruction on the VME Guides in order to publish it for September 2015.

6. Other Matters

The Chair noted that Hans-Joachim Rätz resigned as Associate Editor for the Journal this past January, 2015. His field of expertise was in vertebrate fisheries. Lisa Hendrickson (USA) has agreed to join the journal's editorial board. Her knowledge of invertebrate biology and stock assessment are a welcome addition to the editorial board.

a) Journal of the Northwest Atlantic Fisheries Organization – Instructions for authors

Our new associate editor, Lisa Hendrickson, has taken a closer look at the information in the JNAFS webpages, particularly the instructions to authors and proposed changes to that could clarify what is needed and improve functionality of the website. Lisa described some of her ideas and STACPUB supported making these changes.

STACPUB **recommends** that a committee (comprised of STACPUB chair, the General Editor and those Associate Editors who are available) be created to review and update the JNAFS website and that the NAFO Secretariat will implement the changes requested.

b) JNAFS Symposium Volumes

STACPUB discussed the possibility of holding another symposium. NAFO SC has not hosted a symposium for several years. They often provide a place for scientists and researchers to share information, with the added benefit of generating additional submissions to JNAFS. It was noted that this was a topic for SC to consider and that the ideas discussed during STACPUB should be compiled and presented to SC later in the meeting.

STACPUB **recommends** that Scientific Council consider holding another symposium and that a list of potential topics and themes would be put forward.

c) Electronic Mailing List and Communication

Some members commented that there was a need for increased communication amongst SC members in order to exchange ideas amongst colleagues and to share information in an informal manner. It was suggested that a group mailing list be created and made available to members. SharePoint could provide a possible solution by having a group distribution list and a notification alert put in place. A future blog or community forum could be created on the new NAFO website for scientists, with a link to an email distribution list. A login would be required for this.

STACPUB **recommends** that the NAFO Secretariat look into this matter, update their current list of SC members and create a forum for the electronic exchange of ideas that is accessible to SC members.

7. Adjournment

The Chair thanked the participants for their valuable contributions, the rapporteur for taking the minutes and the Secretariat for their support. The meeting was adjourned at 10:00 on 11 June 2015.

APPENDIX III. REPORT OF THE STANDING COMMITTEE ON RESEARCH COORDINATION (STACREC)

Chair: Kathy Sosebee

Rapporteur: Lisa Hendrickson

The Committee met at Sobey School of Business, Saint Mary's University, Halifax, NS, Canada, on various occasions throughout the meeting to discuss matters pertaining to statistics and research referred to it by the Scientific Council. Representatives attended from Canada, Denmark (Faroes & Greenland), European Union (Germany, Portugal and Spain), France (in respect of St. Pierre et Miquelon), Japan, Russian Federation and United States of America. The Scientific Council Coordinator and other members of the Secretariat were in attendance.

1. Opening

The Chair opened the meeting at 1115 hours on 30 May 2015, welcomed all the participants and thanked the Secretariat for providing support for the meeting. The Committee also met on 3 June 2015 and 9 June 2015 to review unfinished agenda items. The report was reviewed and adopted on 11 June.

2. Appointment of Rapporteur

Lisa Hendrickson was appointed as rapporteur.

3. Review of Recommendations in 2014

There were no recommendations from 2014.

4. Fishery Statistics

a) Progress report on Secretariat activities in 2014/2015

i) STATLANT 21A and 21B

In accordance with Rule 4.4 of the Rules of Procedure of the Scientific Council, as amended by Scientific Council in June 2006, the deadline dates for this year's submission of STATLANT 21A data and 21B data for the preceding year are 1 May and 31 August, respectively. The Secretariat produced a compilation of the countries that have submitted to STATLANT and made this available to the meeting (Table 4).

106

* Data was not submitted in advance of the June SC meeting, however information on catches was available from the CAT reports submitted to the Secretariat.

5. Research Activities

a) Biological Sampling

i) Report on activities in 2014/2015

STACREC reviewed the list of Biological Sampling Data for 2014 (SCS Doc. 15/11) prepared by the Secretariat and noted that any updates will be inserted during the summer, prior to finalizing the SCS Document which will be finalized for the September 2015 Meeting.

ii) Report by National Representatives on commercial sampling conducted

Canada-Newfoundland (SCS Doc. 15-08, 15-11, 14-08 plus information various SC assessment documents): Information was obtained from the various fisheries taking place in all areas from Subareas 0, 2, 3 and portions of Subarea 4. Information was included on fisheries and associated sampling for the

following stocks/species: Greenland halibut (SA 0 + 1 (except Div. 1A inshore), SA 2 + Divs. 3KLMNO), Atlantic salmon (SA 2+3+4), Arctic charr (SA 2), Atlantic cod (Divs. 2GH, Divs. 2J+3KL, Divs. 3NO, Subdiv. 3Ps), American plaice (SA 2 + Div. 3K, Divs. 3LNO, Subdiv. 3Ps), witch flounder (Divs. 2J3KL, 3NO, 3Ps), yellowtail flounder (Divs. 3LNO), redfish (Subarea 2 + Divs. 3K, 3LN, 3O, 3P4V), northern shrimp (Subarea 2 + Divs. 3KLMNO), Iceland scallop (Divs. 2HJ, Divs. 3LNO, Subdiv. 3Ps, Div. 4R), sea scallop (Div. 3L, Subdiv. 3Ps), snow crab (Divs. 2J+3KLNO, Subdiv. 3Ps, Div. 4R), squid (SA 3), thorny skate (Divs. 3LNOPs), white hake (Divs. 3NOPs), lobster (SA 2+3+4), capelin (SA 2 + Divs. 3KL), and marine mammals (SA 2-4). A provisional sampling report was submitted to the Secretariat noting sampling of catches for length distribution and age for Cod, Redfish, Haddock, American plaice, Greenland halibut, Witch flounder and White Hake. These data are provisional due to data formatting and quality control issues as a result of implementing a new process for delivery of the Observer Program on April 1, 2013. This provisional status applies to and the 2014 sampling (SCS Doc. 15-11) and also the 2013 sampling (SCS Doc. 14-08). Once these data are finalized, the inventory will be updated.

109

Denmark/Greenland (SCS Doc. 15-10): Length frequencies were available from the Greenland trawl fishery in Div. 1A and 1D. CPUE data were available from the Greenland trawl fishery in Divs. 1AB and 1CD.

EU-Estonia (SCS Doc. 15-04): Estonia collected length frequencies for Greenland halibut in Divs. 3L and 3N, Northern shrimp in Div. 3L, redfish in Divs. 3L, 3M, 3N and 3O, cod in Div. 3M, American plaice in Div. 3M and 3N, and yellowtail flounder in Div. 3N. Samples were done on both directed species and discards.

EU-Portugal (SCS Doc. 15-006): Data on catch rates were obtained from trawl catches for redfish (Divs. 3LMNO), Greenland halibut (Divs. 3LMN), cod (Div. 3M) Thorny skate (Div. 3N), roughhead grenadier (Div. 3N) and white hake (Div. 3O). Data on length composition of the catch were obtained for Cod (Divs. 3LMNO), redfish *S. mentella* (Divs. 3LMNO) American plaice (Divs. 3LMNO), Greenland halibut (Divs. 3LMN), witch flounder (Divs. 3MNO), roughhead grenadier (Divs. 3LMN), redfish *S. marinus* (Div. 3M), thorny skate (Div. 3M) and white hake (Div. 3O).

EU-Spain (SCS Doc. 15-005): A total of 12 Spanish trawlers operated in Divs. 3LMNO NAFO Regulatory Area during 2014, amounting to 1,205 days (18,271 hours) of fishing effort. Table 3 presents the Spanish effort (fishing hours) since 2003 in NAFO Regulatory Area (NRA) Subarea 3. Total catches for all species combined in Divs. 3LMNO were 14 318 t in 2014. In addition to NAFO observers (NAFO Observers Program), 8 IEO scientific observers were onboard Spanish vessels, comprising a total of 303 observed fishing days, around 25% coverage of the total Spanish effort. Besides recording catches, discards and effort, these observers carried out biological sampling of the main species taken in the catch. For Greenland halibut, roughhead grenadier, American plaice and cod this includes recording weight at length, sex-ratio, maturity stages, performing stomach contents analyses and collecting material for reproductive studies. Otoliths of these four species were also taken for age determination. In 2014, 582 length samples were taken, with 65,437 individuals of different species examined to obtain the length distributions.

Two Spanish trawlers operated in NAFO Regulatory Area, Div. 6G using a midwater trawl gear, during 2014, amounting to 15 days (117 hours) of fishing effort. The most important species in catches was the *Beryx splendens*. Other species present in catches were *Ruvettus pretiosus*. There were not available Spanish catches length distribution in Div. 6G in 2014.

Russia (SCS 15/07): Biological data on Greenland halibut from Divs. 1A and 1D were collected by observers aboard Russian fishing vessels.

Biological data were collected by NAFO observers on fishing vessels for these species:

Greenland halibut (Reinhardtius hippoglossoides) Divs. 3L, 3M and 3L, , Acadian redfish (Sebastes fasciatus) Div. 3N, Deep-sea redfish (Sebastes mentella)Divs. 3L, 3M, 3N, 3O, Golden redfish (Sebastes marinus) Divs. 3L and 3M, Roughhead grenadier (Macrourus berglax) Divs. 3L and 3M, Roundnose grenadier (Coryphaenoides rupestris) Div. 3L, American plaice (Hippoglossoides platessoides) Divs. 3L, 3M 3N and 3O, Witch flounder (Glyptocephalus cynoglossus) Divs. 3L, 3M, 3N and 3O, Cod (Gadus morhua)Disv. 3L, 3M, 3N, and 3O, White hake (Urophycis tenuis)Divs. 3N and 3O, Thorny skate (Amblyraja radiata) Div. 3L, Black dogfish (Centroscyllium fabricii)Subarea 3, Northern wolffish (Anarhichas denticulatus) Divs. 3L and 3M, Atlantic wolffish (Anarhichas lupus) Div. 3M, Spotted wolffish (Anarhichas minor) Div. 3M, Blue hake (Antimora rostrata) Div. 3L, Marlin-spine grenadier (Nezumia bairdii) Div. 3L, Atlantic halibut (Hippoglossus hippoglossus) Divs. 3LMN.

b) Biological Surveys

i) Review of survey activities in 2014 (by National Representatives and Designated Experts)

Canada-Newfoundland (SCR Doc. 15/22): Research survey activities carried out by Canada (N) were summarized, and stock-specific details were provided in various research documents associated with the stock assessments. The major multispecies surveys carried out by Canada in 2014 include a spring survey of Divs. 3LNO, and an autumn survey of Divs. 2HJ3KL.

The spring survey in Divs. 3LNO was conducted from late March to late June, and consisted of 254 successful tows (300 planned) covering all 84 planned strata to a maximum depth of 732m with the Campelen 1800 trawl, by the research vessel CCGS Alfred Needler. This survey continued a time series begun in 1971. The 46 set reduction was required primarily due to mechanical issues and completion of the reduced survey also required the deployment of CCGS Teleost which is not the usual vessel conducting the spring surveys. In addition, Divs. 3NO was covered about two weeks later than normal.

The autumn survey was conducted from early October and extended to January 2015 in Divs. 2HJ3KL, and consisted of 503 tows (674 planned) covering 147 of 208 planned strata to a maximum depth of 1500m in 2HJ3KL and 732m in 3NO with the Campelen 1800 trawl. The reduction was due to the unavailability of CCGS Alfred Needler because of mechanical issues, requiring the *apriori* elimination of Divs. 3NO and deep water strata in 2H for a total of 161 stations. The vessel CCGS Teleost conducted the Divs. 2HJ3KL survey, which continued a time series begun in 1977.

Denmark/Greenland (SCR Docs. 15/01, 03, 16, 31; SCS Doc. 15/10): The West Greenland standard oceanographic stations were surveyed in 2014 as in previous years (SCR Doc. 15/01).

A series of annual stratified-random bottom trawl surveys, mainly aimed at shrimps, initiated in 1988 was continued in 2014. The gear was changed in this survey in 2005. No correction for this gear change has been made and the 2005 - 2012 time series is hence not directly comparable with 1988-2004 time series. In July-August 211 research trawl hauls were made in the main distribution area of the West Greenland shrimp stock, including areas in Subarea 0 and the inshore areas in Disko Bay and Vaigat. The surveys also provide information on Greenland halibut, cod, demersal redfish, American plaice, Atlantic and spotted wolffish and thorny skate (SCR Doc. 15/16).

A Greenland deep sea trawl survey series for Greenland halibut was initiated in 1997. The survey is a continuing of the joint Japanese/Greenland survey carried out in the period 1987-95. In 1997-2014 the survey covered Divs. 1C and 1D between the 3 nautical mile line and the 200 nautical mile line or the midline against Canada at depths between 400 and 1 500 m. In 2013 only Div. 1D was covered by 27 hauls and the survey is and the survey is not considered reliable for estimating indices for stock status . In 2014 58 valid hauls were made (SCR Doc. 15/03).

A longline survey for Greenland halibut in the inshore areas of Disko Bay, Uummannaq and Upernavik was initiated in 1993. In 2014 the longline survey was conducted in Uummannaq (23 sets) and Upernavik (16 set). In connection to the longline survey 4 and 13 gill net were set in Uummannaq and Upernavik, respectively. Each gillnet was composed of four panels with different mesh size (46, 55, 60 and 70 mm stretch meshes) as in Disko Bay (SCR Doc. 15/31).

Since 2001 a gillnet survey has been conducted annually in the Disko Bay area. In 2014 a total of 37 gillnet settings were made along 4 transect. No gill net survey in 2009 (SCR Doc. 15/31).

EU-Spain and Portugal (SCR Doc. 15/17): The EU bottom trawl survey in Flemish Cap (Div. 3M) was carried out on board R/V Vizconde de Eza using the usual survey gear (Lofoten) from June 25th to July 23th 2014. The area surveyed was Flemish Cap Bank to depths up to 800 fathoms (1460 m) following the same procedure as in previous years. The number of hauls was 183 and two of them were nulls. Survey results including abundance indices of the main commercial species and age distributions for cod, redfish, American plaice, roughhead grenadier and Greenland halibut are presented as Scientific Council Research documents. Flemish Cap survey results for northern shrimp (Pandalus borealis) were presented in SCR Doc. 14/49. Samples for histological assessment of sexual maturity of cod, redfish, Greenland halibut and roughhead grenadier were taken. Oceanography studies continued to take place.

NEREIDA Project: New data on deep-water corals and sponges were presented based on Spanish/EU bottom trawl groundfish surveys for 2014 in order to make these data available to the NAFO WGESA and improve the mapping of sensitive species in the NAFO Regulatory area (Divs. 3LMNO).

111

"Significant" catches (according to the NAFO definition from groundfish surveys) of deep-water corals and sponges were provided and mapped together with the closed areas. A total number of 411 bottom trawl hauls surveys were analyzed. Distribution maps of presence and catches above threshold for RV data of sponges, large gorgonians, small gorgonians and sea pens following the thresholds were presented.

Sponges were recorded in 198 of the total tows (48% of the total Spain/UE tows analyzed). Catches above the identification threshold for RV data (\geq 75 kg/tow) were found in 8 tows. Of the total 8 tows, only 1was recorded outside of the closed areas. Large gorgonians were recorded in 4 tows (1% of the total tows analyzed). One catch above the identification threshold for RV data (> 0.6 kg/tow) was found with a weight of 34.3 kg; small gorgonians were recorded in 39 tows (9% of the total tows analyzed). No catches above the identification threshold for RV data (> 0.15 kg/tow) were recorded and finally, sea pens were recorded in 151 tows (37% of the total tows analyzed). Catches above the identification threshold for RV data (> 1.4 kg/tow) were found in 2 tows located inside closed areas 9 and 10.

In addition, and as part of the NEREIDA project, biological samples collected using mega box-core were analyzed and processed for the extraction and identification of benthic fauna. Analysis of the extracted data revealed the presence of benthic assemblages that were indicative of Vulnerable Marine Ecosystems (VME). VME indicative assemblages were present mostly outside of the fishing footprint in the area of study. A simple habitat suitability model has been performed to ascertain areas that are likely to accommodate VME indicative assemblages. Areas with the greatest potential to accommodate VME assemblages closely correspond with areas already managed for the protection of VME, where bottom-contact fishing practices are presently excluded.

USA (SCS Doc. 15/09): The USA conducted a spring survey in 2014 covering NAFO Subareas 4, 5 and 6 aboard the FSV *Henry B. Bigelow*. In 2014, the spring survey did not cover a large portion of the Mid-Atlantic region and this has impacted the survey indices for summer flounder, southern red hake, Atlantic mackerel, Atlantic herring, spiny dogfish and little skate. The US conducted an autumn survey in 2014 covering NAFO Subareas 4, 5 and 6 aboard the FSV *Henry B. Bigelow*. All planned strata were covered. Biomass indices were presented for many stocks and abundance for the two squid stocks.

ii) Surveys planned for 2014 and early 2015

Information was presented and representatives were requested to review and update before finalization of an SCS document in September.

iii) Report on data availability for stock assessments (by Designated Experts)

Designated Experts were reminded to provide available stock assessment data from commercial fisheries and research surveys to the Secretariat. It was agreed to store the files on the meeting SharePoint under a folder entitled "DATA".

c) Tagging Activities

STACREC **recommends** that the NAFO Secretariat develop a framework for communicating tagging study information to vessels from Contracting Parties and Coastal States fishing in the Convention Area (e.g., via a link to this information on the NAFO website homepage).

d) Other Research Activities

There were no other research activities presented during the STACREC meeting.

6. Review of SCR and SCS Documents

USA (SCS Doc. 15-009): The report described catches and survey indices of 37 stocks of groundfish, invertebrates and elasmobranchs. It was noted that the fishery for shrimp in the Gulf of Maine was closed in 2014. Research on the environment, plankton, finfishes, marine mammals, and apex predators were described. A description of cruises to map deep sea corals in canyons off the southern edge of George Bank was given. Other studies included age and growth, food habits, and tagging studies. The number of observer

trips by fishery was discussed as well as cooperative research with the industry. A description of the method for estimating catches in the observer program used both in US waters and in the NRA was given.

7. Other Matters

a) Stock Assessment Spreadsheets

Designated Experts were reminded to include their spreadsheets under the DATA tab on the SharePoint. It was agreed to at least start with the stocks that were fully assessed.

b) OBIS

Bob Branton (Dalhousie University, Canada) gave a brief overview of OBIS and requested those with historic datasets to consider submitting them. An abstract of the presentation is printed below:

The Ocean Biogeographic Information System (OBIS), originally created by the Census of Marine Life, is now part of the Intergovernmental Oceanographic Commission (IOC) of UNESCO, under its International Oceanographic Data and Information Exchange (IODE) programme. Previous OBIS Canada presentations to Northwest Atlantic Fisheries Organization (NAFO) scientists (STACFEN 2012, STACREC 2014) were generally focused on: What is OBIS?: What can NAFO do for OBIS?: What can OBIS do for NAFO?: and Data management best practices & tools. As of April, 2015, OBIS is providing unrestricted public access to five NAFO data collections (Table 4). Using one of these collections (OBISid 3460), an ArcGIS Online Map of 'NAFO: Historical collection of annual fisheries catch statistics for cod, haddock and redfish ...' is now publicly available. In May 2015, OBIS Canada presented a poster to the Oceans Past V Conference in Tallinn Estonia, titled 'A public Geographic Information System for historic Canadian groundfish and small pelagic tagging studies conducted west of Newfoundland in the years 1953- 1999'. By way of these recent developments we wish to generally promote ongoing OBIS Canada/NAFO cooperation and to particularly encourage contribution of any and all. past and present Northwest Atlantic groundfish and small pelagic tag releases and recaptures to the nearest Regional OBIS Node.

Table 5.	NAFO data resources on OBIS as of April 2015.	
Tuble 5.	inn o data resources on obio as of ripril 2015.

NAFO: Historical collection of annual fisheries catch statistics for flatfish in the Northwest Atlantic during the period 1893-1959.	614	8	1893 - 1959

c) Involvement of NAFO Scientific Council in a Horizon 2020 proposal ("AFOOD")

Scientific Council discussed the request from the proponents of an EU H2020-BG02-2015 proposal "Predicting consequences of climate change on Aquatic FOOD production (AFOOD)". The proposal is within the call BG2 about "Forecasting and anticipating effects of climate change on fisheries and aquaculture". The proponents request Scientific Council of NAFO to participate in an external advisory board to monitor the progress of the project, provide advice when the members of the Board find necessary, and produce short interim reports evaluating the results of the project.

AFOOD will study the impacts of climate change on both capture fisheries and aquaculture. The proposals aims to model how environmental changes and exploitation have affected production dynamics of aquatic species and communities over the past decades and use this information in the forecasting of future climate change impacts. Two of the proposed case studies involve NAFO managed stocks.

STACREC discussed the request and concluded that if successful the project could provide information that could be useful in the provision of scientific advice on NAFO managed stocks and *recommended that* the Scientific Council support EU H2020-BG02-2015 proposal "Predicting consequences of climate change on Aquatic FOOD production (AFOOD)" and agree to serve on the external advisory board. Ricardo Alpoim (EU-Portugal) was proposed as the SC representative on this external advisory board.

8. Adjournment

The Chair thanked the participants for their presentations to the Committee. Special thanks were extended to the rapporteur and the Scientific Council Coordinator and all other staff of the NAFO Secretariat for their invaluable assistance in preparation and distribution of documents. There being no other business the Chair adjourned the meeting at 1300 hours on 11 June 2015.

4.4

Chair: Brian Healey

Rapporteurs: Various

I. OPENING

The Committee met at the Sobey School of Business, Saint Mary's University, Halifax, NS, Canada, from 29 May to 11 June 2015, to consider and report on matters referred to it by the Scientific Council, particularly those pertaining to the provision of scientific advice on certain fish stocks. Representatives attended from Canada, Denmark (in respect of the Faroe Islands and Greenland), the European Union (France, Portugal, Spain and the United Kingdom), Japan, Norway, the Russian Federation, and the United States of America. Various members of the Committee, notably the designated stock experts, were significant in the preparation of the report considered by the Committee.

The Chair, Brian Healey (Canada), opened the meeting by welcoming participants. The agenda was reviewed and a plan of work developed for the meeting. In accordance with the Scientific Council plan of work, designated reviewers were assigned for each stock for which an interim monitoring update was scheduled (see SC Report). The provisional agenda was adopted with minor changes.

II. GENERAL REVIEW

1. Review of Recommendations in 2014

STACFIS agreed that relevant stock-by-stock recommendations from previous years would be reviewed during the presentation of a stock assessment or noted within interim monitoring report as the case may be and the status presented in the relevant sections of the STACFIS report.

2. General Review of Catches and Fishing Activity

STACFIS conducted a general review of catches in the NAFO SA 0–4 in 2014. In contrast to most recent years, there was no ad-hoc working group convened to consider catch estimates before the meeting, as there was no indication that any new sources of data or methods for catch estimation were available. NAFO Scientific Council (STACFIS) has estimated catch for its stock assessments for many years since the 1980s when large discrepancies were observed between various sources of catch information. The goal of this exercise was to use the best information available to provide the best possible assessments and advice. STACFIS has had available estimates from different sources, but not for all fleets or from all Contracting Parties. These various sources of data have in many years led STACFIS to the conclusion that catch estimates from STATLANT have been unreliable for a number of stocks. Lack of catch estimates is hindering provision of advice for many stocks, and for other cases, the accuracy of assessment results and management advice rely on the assumption that the STATLANT data equals the annual landings, an assumption which can no longer be independently verified. STACFIS noted that the *Ad hoc* FC-SC Working Group on Catch Reporting (WG-CR) continues its mandate and that more detailed reporting requirements have been implemented within NAFO (e.g. catch reporting on a tow-by-tow basis introduced as of Jan 1 2015).

Key sources of other data have not been available to evaluate STATLANT data since 2011.

During the June 2015 SC meeting, the only sources of catch information for 2014 were national research reports, STATLANT 21A data and Daily Catch Records (DCR) for fleets which operated in the NRA. It was noted that STATLANT 21A data was not available for all contracting parties by the start of the meeting, therefore only data available as of 30 May was considered. Data on effort from both STATLANT 21B and the VMS reporting were also available, and considered as a means to evaluate the plausibility of trends in recent catches reported within STATLANT21. STACFIS agreed to a general procedure whereby STATLANT21A data were accepted to estimate catch where available. For those countries which had not reported STATLANT21A, the DCR were used to estimate the 2014 catches. There were two exceptions to this procedure: American Plaice in Divs. 3LNO and Greenland Halibut in SA2+Divs. 3KLNO. The 2014 assessment of American Plaice in Divs. 3LNO used an assumption of constant CPUE over 2011-2013 to estimate catch of some fleets. At that time it was noted this procedure was unlikely to be useful in future. Consideration was given to estimating 2014 catches as there was new information presented on catch and effort, but STACFIS was unable to continue using the effort method used to derive catch for 2014 without further investigation. Therefore it

was agreed to consider catch estimation options for this stock during the next assessment. For Greenland Halibut, STACFIS examined trends in effort over 2010-2014 as estimated from VMS data. Considering that catch per unit effort has remained relatively high over this period, the observed declines in effort from 2010 to 2014 were not sufficient to explain the apparent decline in the catch estimated by STACFIS in 2010 relative to that reported in the STATLANT catch for 2014. Therefore STATLANT catch was not accepted as an estimate of catch on this stock in 2014. There are no estimates of catch for this stock over 2011-2014, preventing updated estimates of stock size and reevaluation of the management strategy.

Unavailability of accurate catch data also has implications on the potential to provide quantitative assessments for stocks that are currently assessed qualitatively. Several classes of population dynamics models will have poor diagnostics if the removals data are biased and are inconsistent with changes in survey trends. Consequently, estimation of population size and any resulting management options using biased catch data will be inaccurate.

. A. A

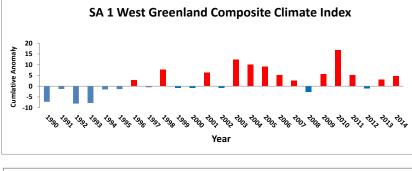

A. STOCKS OFF GREENLAND AND IN DAVIS STRAIT: SA0 AND SA1

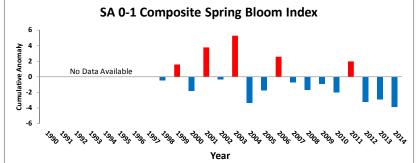

(SCR Docs. 15/01, 02; SCS Doc. 15-10)

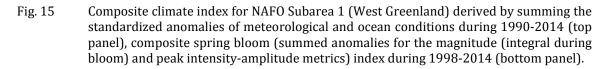

Recent Conditions in Ocean Climate and Lower Trophic Levels

• The composite climate index in Subarea 1 has remained above or near normal in recent years but has trended downward from the record-high in 2010.

• The composite spring bloom index remains well below normal since 2012.

Environmental Overview

Hydrographic conditions in West Greenland Waters depend on a balance of atmospheric forcing, advection and ice melt. Winter heat loss to the atmosphere in the central Labrador Sea is offset by warm water carried northward by the offshore branch of the West Greenland Current. The water mass circulation off Greenland comprises three main currents: Irminger Current (IC), West Greenland and East Greenland Currents (WGC and EGC). The EGC transports ice and cold low-salinity Surface Polar Water (SPW) to the south along the eastern coast of Greenland. The IC is a branch of the North Atlantic current and transports warm and salty Atlantic Waters northwards along the Reykjanes Ridge. The core properties of the water masses of the WGC are formed in the western Irminger Basin where the EGC meets the IC. After the currents converge, they turn around the southern tip of Greenland, forming a single jet (the WGC) that propagates northward along the western coast of Greenland. The WGC consists thus of two components: a cold and fresh inshore component, which is a mixture of the SPW and melt water, and saltier and warmer ISW offshore component. The WGC transports water into the Labrador Sea and, hence, is important for Labrador Sea Water formation, which is an essential element of the Atlantic Meridional Overturning Circulation (AMOC).

Ocean Climate and Ecosystem Indicators

The composite climate index in Subarea 1 has remained above or near normal in recent years but has trended downward from the record-high in 2010. (Fig. 15). Cold, fresh conditions persisted in the early to mid-1990s followed by a general warming trend in the past decade with the exception of a brief cooling event in 2008. The composite spring bloom index in Subareas 0-1 remains below normal since 2012. In winter 2013/14, the North Atlantic Oscillation (NAO) index was strongly positive resulting in increased westerlies over much of the North Atlantic Ocean. Often this results in colder conditions over the West Greenland region but has not been the case in 2014 with annual air temperature remaining above normal at Nuuk. The time series of mid-June temperatures at Fylla Bank show temperatures 0.8°C above average in 2014 and salinities above average by 0.22.

117

1. Greenland Halibut (Reinhardtius hippoglossoides) in SA 0, Div. 1A offshore and Divs. 1B-F

(SCR Docs. 15/03, 16, 24, 25, 30, 32, 35; SCS Docs. 15-07, 08, 10)

a) Introduction

The Greenland halibut stock in Subarea 0 + Div. 1A offshore and Divs. 1B-1F is part of a common stock distributed in Davis Strait and southward to Subarea 3. Since 2001 advice has been given separately for the northern area (Div. 0A and Divs. 1AB) and the southern area (Div. 0B and Divs. 1C-F).

A TAC was first established for SA 0+1, including Div. 1A inshore, in 1976 and set at 20 000 t. It increased to 25 000 t in 1979 and remained at this level until 1994. In 1994 Scientific Council decided to make separate assessments and advice for the inshore area in Div. 1A and for SA 0 + Div. 1A offshore + Divs.1B-1F. As a result the TAC for SA 0 + Div. 1A offshore + Divs.1B-1F decreased to 11 000 t and remained at this level until 2001. Between 2001 and 2014 the TAC increased to 30 000 t following a series of new surveys in previously unassessed areas of Divs. 0A and 1AB and improving stock status in Divs. 0B and 1CD. Since 2001 the TAC has been divided between Divs. 0A+1AB and Divs. 0B+1C-F with current levels of 16 000 t for Divs. 0A+1AB and 14 000 t for Divs. 0B+1CD (Fig. 1.1).

Catches in 0 + Div. 1A offshore + Divs.1B-1F increased from low levels during the late 1960s to 20 000 t in 1975 before declining and remaining relatively stable at approximately 4 500 t during the 1980s. Catches increased again between 1989 and 1992, reaching a peak of almost 20 000 t before declining to 11 800 t in 1994. Catches were relatively stable at approximately 8 500 t from 1995 to 2000 with almost all the catch coming from Div. 0B and Divs. 1CD. Since then catches have increased to current levels of 31 100 t with the TAC achieved in most years (Fig. 1.1).

The fishery in Subarea 0. Catches increased from 400 t in 1987 to 12 800 t in 1992 but decreased to 4 700 t in 1992 and stayed at that level until 2000. Prior to 2001 almost all the fishery has been taking place in Div. 0B and fishing occurred in only a few years between 1993 and 2000 with catches of less than 700 t in Div. 0A. In 2001 catches increased to 8 100 t due to increased effort in Div. 0A. Since then catches have increased gradually to 14 900 t in 2014 following increase in TAC mainly in Div. 0A but also in Div. 0B. In recent years all catches have been taken by vessels from Canada and approximately 1/3 has been taken by gill net and 2/3 by single and twin trawlers.

The fishery in Div. 1A offshore + Divs. 1B-1F. In SA1 catches fluctuated between 1 800 and 5 700 t between 1987 and 2001 and almost all of the catches have been taken in Divs. 1CD. A fishery was started in Divs. 1AB in 2000 and catches increased gradually to 9 500 t in 2003. Catches remained at that level until 2005. Since then catches have increased gradually to 16 100 t in 2014 following increase in TAC mainly in Divs. 1AB but also in Divs. 1CD. In recent years the offshore fishery has been prosecuted by twin and single trawlers from Greenland, Norway, Russian Federation, Faroe Islands and EU (mainly Germany). Inshore catches in Divs. 1B-1F has been around 200-300 t annually but increased from 440 t in 2012 to 1 800 t in 2014 mainly due to increased effort in Div. 1D (Fig. 1.1).

¹ Excluding inshore catches in Div. 1A

² Excluding 2 000 – 4 300 t reported by error from Div. 1D

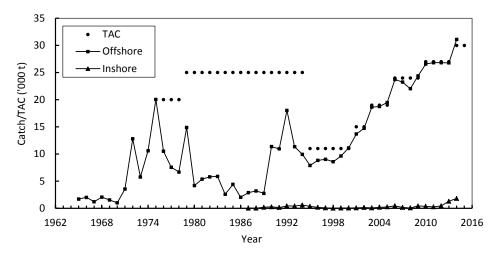

Fig. 1.1. Greenland halibut in Subareas 0+1 (excluding Div. 1A inshore): catches and TACs.

b) Input Data

i) Commercial fishery data

Length frequencies were not available from Canadian fisheries in 2013 and 2014.

Length frequencies were available from trawl fisheries by Greenland and Russian Federation in Div. 1A and from Norway and Greenland in Div. 1D. In 2014 catch from Greenland and Russian Federation in Div. 1A had modes at 50 cm. In recent years the trawl catches have been dominated by fish of 44-52 cm. In Div. 1D the catches Norway and Greenland showed modes around 50-55 cm. The mode in catches has been between 49 and 55 cm for many years.

The standardized trawl CPUE series for Divs. 0A+1AB combined has been stable since 2002 with an increasing trend since 2007 (Fig. 1.2). Catch rates before 2001 are from only one or two vessels fishing a small exploratory allocation and may not be directly comparable to subsequent years.

The standardized trawl CPUE series for Divs. 0B+1CD combined was relatively stable from 1990-2004, increased from 2004-2009 then decreased between 2009 and 2012 but increased again in 2013 and 2014 and the 2014 estimate is among the highest seen since 1989. (Fig.1.2). Catch rates in 1988 and 1989 are from one 4000 GT vessel fishing alone in the area and may not be directly comparable to subsequent years.

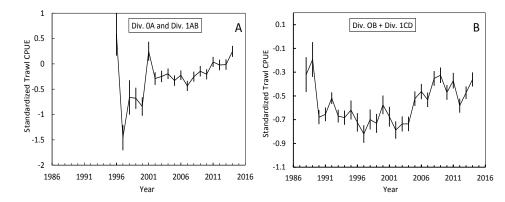

Fig. 1.2. Greenland halibut in Subareas 0+1 (excluding Div. 1A inshore): Combined standardized trawler CPUE \pm S.E from Div. 0A and Divs. 1AB (panel A) and Div. 0B and Divs. 1CD. (panel B).

A standardized CPUE index for all trawlers fishing in SA 0+1 increased between 2002 and 2006 and has been fluctuating with an increasing trend since then. The 2014 estimate was the largest seen since 1990. (Fig. 1.3). Standardized CPUE for gillnets in Div. 0A increased gradually from 2006-2011 and has been stable since then (Fig. 1.4).

Standardized CPUE for gill nets in Div. 0B has been gradually increasing since 2007 and was at the highest level in the time series in 2014 (Fig. 1.4).

It is not known how the technical development of fishing gear or vessel changes in the fleets has influenced the catch rates. There are indications that the coding of trawl gear type in the log books is not always reliable, which also can influence the estimation of the catch rates, therefore, the catch rates should be interpreted with caution.

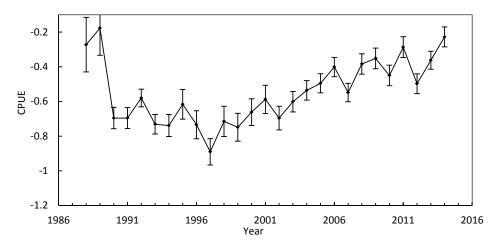

Fig. 1.3. Greenland halibut in Subareas 0+1 (excluding Div. 1A inshore). Combined standardized trawler CPUE from all divisions with ± S.E.

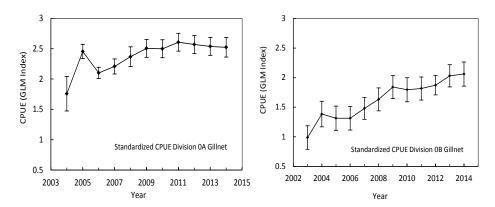

Fig. 1.4. Greenland halibut in Subareas 0+1 (excluding Div. 1A inshore): Standardized gillnet CPUE from Div. 0A (left) and Div. 0B (right).

ii) Research survey data

Japan-Greenland and Greenland deep sea surveys in Divs. 1BCD. From 1987-95 bottom trawl surveys were conducted in Divs. 1BCD jointly by Japan and Greenland (the survey area was re-stratified and the biomass estimates were recalculated in 1997). The Japan-Greenland survey in 1987 only covered depths down to 1000 m and the biomass at depths 1000-1500 m is estimated by a GLM. In 1997 Greenland initiated a new survey series covering Divs. 1CD. This index of trawlable biomass has been variable with a gradually increasing trend since 1997. 2011 was the highest in the time series but the biomass has been decreasing gradually since then and the 2014 estimate was the lowest seen since 1997 (Fig. 1.5).

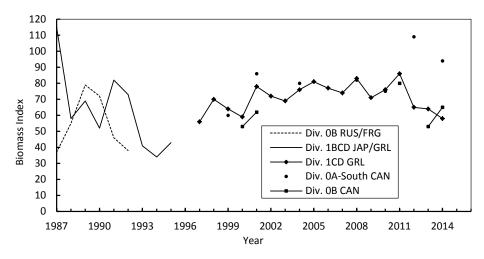

Fig. 1.5. Greenland halibut in Subareas 0+1 (excluding Div. 1A inshore): biomass indices from bottom trawl surveys. A survey in Div. 0A in 2006 is not included due to poor coverage.

Canada deep sea survey in Div. 0A-South. The survey biomass indices were recalculated in 2014 based on a new stratification scheme (SCR Doc. 15/30). The index of trawlable biomass for Div. 0A-South has been fluctuating with a slight increasing trend since 1999. The 2012 estimate was the highest of the time series. The biomass index decreased slightly between 2012 and 2014(Fig. 1.5). Lengths ranged from 6-78 cm with minor modes at 18 and 33 cm that may reflect the high abundance of 2011 and 2013 year classes. The primary mode was 45 cm, slightly higher than seen in previous surveys. The proportion of fish <45cm has declined from approximately 70% in 2008 to 54% in 2014. The abundance of fish 40-60 cm has increased since 2010.

Canada deep sea surveys in Div. 0B. The survey biomass indices were recalculated in 2014 based on a new stratification scheme. Div. 0B was surveyed in 2014 for the fifth time by R/V *Pâmiut*. Previous surveys were conducted in 2000, 2001, 2011 and 2013. Biomass decreased in 2013 compared to 2011 but increased slightly again in 2014 and is at about average for the short survey series (Fig. 1.5). Lengths ranged from 6 cm

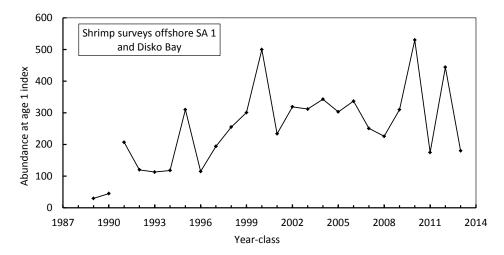

to 90 cm with 18% < 45 cm. The length distribution had a single mode at 48 cm as in the previous two surveys.

121

Div. 0A-South and 1CD combined-stock index. The ICES Benchmark Workshop (ICES 2013) recommended combining the 0A-South and 1CD indices to create a single index with which to monitor the overall stock status. This recommendation was adopted by STACFIS in 2014. The surveys are conducted by the same vessel and gear during the fall which allowed for a simple addition of the survey estimates to create the index (Fig. 1.7). The index has been relatively stable since 2001.

Greenland shrimp and fish survey in Divs. 1A-1F. Since 1988 annual surveys with a shrimp trawl have been conducted off West Greenland during July-September. The survey covers the area between 59°N and 72°30'N (Divs. 1A-1F), from the 3-mile limit to the 600-m depth contour line. The survey only covers a small fraction of the Greenland halibut distribution and catches mainly age one and age two Greenland halibut, therefore the biomass estimate is not used as a stock index but the survey is used to estimate a recruitment index for age one. The trawl was changed in 2005 but the 2005–2014 time series estimates are adjusted to the old 1989-2004 time series and the series are comparable.

The year class index of one-year-old fish in the total survey area, including Disko Bay, was variable for year classes 1989 to 1996 then increased to a peak in 2000 followed by a sharp decline in the 2001 year class. A period of relative stability during the 2000s was followed by an increase to the highest in the time series for the 2010 year class. There was a sharp decrease in the 2011 year class to the lowest estimate since 1996 but this was followed by an increase in the 2012 year class and yet another decrease in the 2013 year class. (Fig. 1.6).

Abundance - all surveys. The length composition is relatively constant in all surveys and the trend in abundance generally follows the trend in biomass index for each series.

c) Estimation of Parameters

In 2014 a simple Schaefer model was tested on the Greenland halibut stock offshore in NAFO SA 0 and 1. The minimum data required for this model is a catch time series and a measure of the resilience of the species. Other input parameters that required a starting guess were the carrying capacity, the biomass as a fraction of the carrying capacity at both the beginning and end of the time series, and the growth rate. MSY was estimated to be between 19 000 and 23 000 t. Sensitivity tests showed that the estimation of MSY was heavily dependent on the guess of especially the biomass at the end of the time series and the growth rate. The model cannot become any more reliable unless we can improve the input parameter "guesses" through a better understanding of the stock dynamics and biology. Until then the outcome of the model is considered only indicative of stock status and not useful for estimating reference points. The model was not tested in 2015.

d) Additional studies

Environmental forcing. A study showed that year class strength and abundance of Greenland halibut at West Greenland may be driven by environmental pulses (of different frequencies):

- (i) The variability in the Sea Surface Temperature (SST_{SD}) in the area of Age 0 drift in the mixing layer is regarded as a system wide variable (a co-factor) for recruitment and abundance. Different trends in SST means and the variability is considered as a key co-factor for recruitment.
- (ii) The following relationships (p<0.05) were further presented:
- (a) Abundance is the inverse of the SST variation considering a lag of 6 years (assumed to be age when they are fully recruited to the fishable population) and can be estimated for short term management planning (5-6 years in advance). The model indicated low abundance in 2014 and 2018 and a high abundance in 2017. Two cycles at different levels of abundance were identified at different recruitment regimes.
- (b) Recruitment from age class 0 to age class one (with a lag of 5 years) is both related to overall abundance of Greenland halibut and has a higher sensitivity for SSTminima.
- (c) The variation in abundance indices from surveys (both means and variability) showed two clear cycles.
- (iii) The results showed several years of memory and it is highly differentiated from a random process (Hurst exponent >0.75) and residuals were – as in several dynamical systems of such nature- autocorrelated (not random).

These relationships (variability and lag effects) should be considered as an alternative or complement to assessments that use only the Logistic model –or some derivative- which assumes that (a) residuals are random and (b) there is no memory effect in the series (no dependency on preceding values).

The work is still in progress and has not been peer reviewed and is not included in the assessment (SCR Doc. 15/24).

A survey approach to estimate catch level of Greenland halibut in SA 0+1. The assessment of Greenland halibut in Subarea 0 and 1A (offshore)+1B-F relies on several fishery independent survey indices. The application of the ICES guidance on data limited stocks (DLS) (ICES 2012a and 2012b) as the basis for the approach for advice on SA0+1 Greenland Halibut could be helpful in providing TAC advice.

ICES has developed and tested an empirical approach that uses the trend in the stock response to fishing pressure (ICES 2012a). The empirical basis was given a generic expression $C_{y+1}=Catch_{recent}*r$: Catch_{recent} is the average catch over some period, r is the trend in development of the stock (normally SSB) over some period (e.g. 7 year time frame, r=mean of recent 3 year/mean of next 4 years).

Precautionary buffer (e.g. maximum 20% reduction factor applied to r given certain stock conditions relative to reference points).

Change cap (e.g. maximum 20% change in TAC advice in any given year).

Advice should not be made annually; it would apply over some period of time (e.g. 2-3 years) to allow for the delay between action (change in catch) and response (state of the stock). There would be interim assessments and advice on TAC could be given in interim years if a sudden change in stock status is observed.

In the case of Greenland halibut in Subarea 0 and 1 we are not able to estimate SSB (due to survey trawl selectivity) or $F_{msyproxy}$. However, we have stock abundance indexes based on surveys that are used to assess the status of two portions of the stock area, 0A1AB (0A-south survey) and 0B1C-F (1CD survey). We have a biomass index and B_{lim} (see below).

There are seven surveys available from Div. 0A-south and Divs. 1CD combined that cover a 15 year period, 1999, 2001, 2004, 2008, 2010, 2012 and 2014 (the 2006 survey has been dropped due to very poor coverage).

There was some discussion whether we calculate r across 5 or 7 survey points (e.g. 10 or 15 years) or use the data points that fall within the last 5 or 7 calendar years. Also, the Div. 0A survey has moved to an annual cycle (beginning in 2014) so in a year or two the number of years covered by the survey points will change. The change cap limits the rate at which the TAC would change at any one time. There was some consideration as to whether a higher change cap should apply when the stock is declining. Managers would determine the level of risk (change cap and precautionary buffer,) but ICES has provided some guidance (as above) for those cases where management input is not available. It was noted that the precautionary factor would need not apply in the case of SA0+1A (inshore) and 1B-F Greenland halibut given the stock is well above B_{lim} and there have been several recent years with good recruitment. There were no comments on the period of time over which the advice should apply in this case (SCR Doc. 15/35) but it was recognized that there may infrequently be a need for revisions to multi-year advice if sudden declines were observed.

123

e) Assessment Results

Subarea 0 + Division 1A (offshore) + Divisionss. 1B-1F

Fishery and Catches: Catches have increased in response to increases in the TAC from approximately 10 000 t in the late 1990s to approximately 27 000 t during 2010 to 2012 then increased to 31 100 t in 2014. The TAC is 30 000 t in 2015.

Data: Biomass indices from deep sea surveys in 2014 were available from Div. 0A, Div. 0B and Divs. 1CD. Further, biomass and recruitment data were available from shrimp surveys in Divs. 1A-1F from 1989-2014. Length distributions were available from both surveys and the fishery in SA1. Unstandardized and standardized catch rates were available from Divs. 0A, 0B, 1AB and 1CD.

Assessment: No analytical assessment could be performed.

Commercial CPUE indices. A standardized CPUE index for all trawlers fishing in SA 0+1 increased between 2002 and 2006 and has been fluctuating with an increasing trend since then. The 2014 estimate was the largest seen since 1990.

The standardized trawl CPUE series for Divs. 0A+1AB combined has shown an increasing trend since 2007. Standardized CPUE for gillnets in Div. 0A increased gradually from 2006-2011 and has been stable since then.

The standardized trawl CPUE series for Divs. 0B+1CD combined was relatively stable from 1990-2004, increased from 2004-2009 then decreased between 2009 and 2012 but increased again in 2013 and 2014 and is now among the highest seen since 1989. The standardized CPUE for gillnets in Div. 0B has been gradually increasing since 2007 and in 2014 was at the highest level in the time series.

Biomass: The combined Div. 0A-South and 1CD index is stable.

Recruitment: A period of relative stability in the recruitment index (age one) during the 2000s was followed by an increase to the highest in the time series for the 2010 year class. There was a sharp decrease in the 2011 year class to the lowest estimate since 1996 but this was followed by an increase in the 2012 year class followed by yet another decrease of the 2013year class.

Fishing Mortality: Level not known.

State of the Stock: The biomass (combined Div. 0A + Divs. 1CD index) is stable and was well above *B*_{lim} in 2014. Most standardized CPUE indices have been increasing in recent years.

Divs. 0B+1C-F: The biomass index in Div. 0B increased between 2013 and 2014 and is at about average for the short time period. The biomass index for Divs. 1CD has been decreasing since 2011 and was in 2014 at the lowest level seen since 1997. Length compositions in the catches and deep sea surveys have been stable in recent years. Standardized CPUE has decreased between 2009 and 2012 but increased again in 2013 and 2014. The Standardized CPUE for gillnets in Div. 0B has been increasing since 2007 and in 2014 was at the highest level in the time series.

Divs. 0A+1AB: The biomass index decreased slightly between 2012 and 2014 but is still at a high level. Length composition in the 0A-South survey shows minor modes at 18 cm in 2012 and 33 cm in 2014 that may reflect the high abundance of 2011 and 2013 year classes. Length frequencies were not available for the SAO fishery

in 2013 and 2014. Combined Standardized CPUE indices for Divs. 0A and 1AB have been increasing since 2006.

f) Precautionary Reference Points

Age-based or production models were not available for estimation of precautionary reference points. In 2014 a preliminary proxy for B_{lim} was set as 30% of the mean biomass index estimated for surveys conducted between 1997-2012 in Divs. 1CD combined with surveys from 1999-2012 in Div. 0A-South to establish a proxy for B_{lim} for the entire stock (Fig. 1.7).

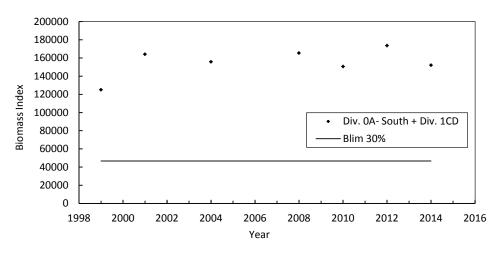

Fig. 1.7. Greenland halibut in Subareas 0+1: Biomass trends in Div. 0A-South and Divs. 1CD and the proxy for B_{lim} .

The next assessment will be in 2016.

2. Greenland Halibut (Reinhardtius hippoglossoides) Div. 1A inshore

Interim Monitoring Report (SCR Docs. 15/16, 31, 39; SCS Doc. 15-10)

a) Introduction

The inshore fishery for Greenland halibut developed in the beginning of the twentieth century, with the introduction of the longline to Greenland in 1910. Greenland halibut is targeted in most inshore areas but the main areas are the Disko Bay and the districts surrounding Uummannaq and Upernavik. Total landings in Subarea 1A-inshore for the three areas combined were less than 1 000 t until 1955 but gradually increased to a level of 5 000 t by 1985. After, the mid-1980s landings increased to 25 000 t in 1999 and remained at a level of 20 000 to 25 000 since then. The stocks are believed to recruit from the spawning stock in the Davis Strait and there is little migration between the subareas. Advice is given for each subarea on a two year basis and a separate TAC is set for each area. Quota regulations were introduced as a shared quota for all vessels in 2008. In 2012, the TAC was split in two components with ITQ's for vessels and shared quota for small open boats. In 2014, "quota free" areas within each subarea were set by the Government of Greenland, and in these areas catches were not drawn from the total quota. The only other significant fishery in the areas is the trawl fishery targeting shrimp in the Disko bay.

Disko Bay: Landings increased from about 2,000 t in the mid 1980's and peaked from 2004 to 2006 at more than 12 000 t. After 2006, landings were halved in just three years without any restrictions on effort, TAC or reduced prices to explain the decrease. Landings have gradually increased since then and in 2014, 9 177 t was landed from the area (Table 2.1 and Fig. 2.1).

Uummannaq: landings increased from 3 000 t in the mid-1980s and peaked in 1999 at more than 8 000 t. Landings then decreased to a level of 5 000 to 6 000 t. After 2005 catches in the area have gradually increased and in 2014 8 199 t were landed (Table 2.1 and Fig. 2.1).

Upernavik: landings increased from the mid-1980s and peaked in 1998 at a level of 7 000 t. This was followed by a period of decreasing landings, but since 2002 catches have gradually increased. In 2014, a record high 7 381 t were landed in the district (Table 2.1 and Fig. 2.1).

	2006	2007	2008	2009	2010	2011	2012	2013	2014	2015

na: no advice.

ni: no increase in effort.

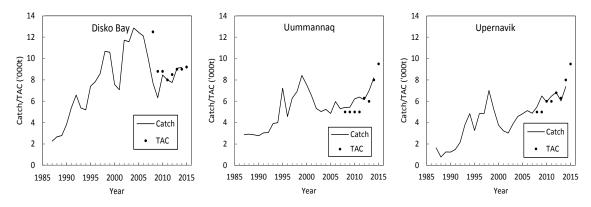

Fig. 2.1. Greenland halibut in Div. 1A inshore: Greenland halibut catches and TAC in Disko Bay, Uummannaq and Upernavik.

b) Commercial fishery data

Length frequencies from factory landings are available since 1993.

In the **Disko Bay**, the mean length in landings from the longline fishery, decreased gradually after 2001 and reached a record low in 2013, but has increased slightly in 2014 (Fig. 2.2). Access to the deep Kangia ice fjord where large Greenland halibut are caught at greater depth is limited during the summer, causing the difference in summer and winter fishery mean length. The trends in the seasons are however decreasing at the same rate over time and the persistent decrease suggests that the decrease was not due to new large

. . . .

incoming year classes. The decreasing mean length in the landings can also be observed in the plotted length distributions from longline landings as a general decrease of all sizes (Fig. 2.3).

In **Uummannaq**, the mean length in longline landings gradually decreased at a slow rate during the past two decades, but stabilized in the most recent years (Fig. 2.2). The increasing mean length in the longline landings can also be observed as an increasing range of sizes in recent years, but the distribution has shifted slightly downward in 2014 (Fig. 2.3).

In **Upernavik**, the mean length in longline landings decreased until 1999, but has been very stable thereafter. In 2014 a size decrease was observed in both the winter and summer fishery. The small fish observed in the 2014 winter fishery may however have been influenced by poor ice conditions during the sampling program where the fishery took place near the settlements in shallower water (Fig. 2.2). The size range in the longline landings were very wide in the beginning of the 1990s, but gradually turned to a more narrow distribution by 2010 (Fig. 2.3). In the more recent years smaller sized fish have increasingly been landed in the area.

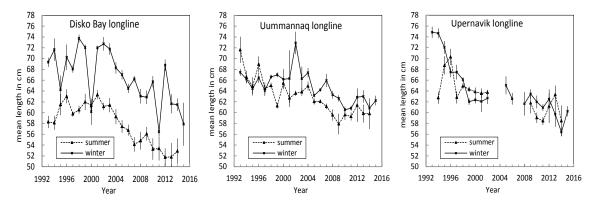

Fig. 2.2. Greenland halibut in Div. 1A inshore: Longline mean length in landings from Disko Bay, Uummannaq and Upernavik.

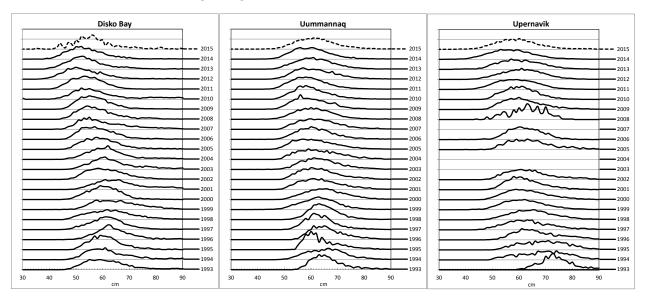

Fig. 2.3 Greenland halibut in Div. 1A inshore: Length frequencies in longline landings (% of number measured).

c) Research survey data

The **Greenland shrimp and fish trawl survey in Disko Bay**: The trawl survey in Disko Bay indicated increasing abundance during the 1990s (Fig. 2.4). After the gear change in 2005 the abundance decreased to low levels in 2008 and 2009, but since then the abundance index has returned to the previous high levels in

2011 and 2013, mainly caused by large 2010 and 2012 year classes. The biomass indices in the trawl survey indicate a steady increase during the 1990s (Fig. 2.4). The new gear indicated an initial decrease, but then returned to a higher level thereafter and peaked in 2011. Since then the biomass index has gradually decreased and the 2014 biomass estimate is the lowest observed in the last decade. The length distribution in the survey reveals that particularly the sizes larger than 25 cm seems to be lower than usual in 2014, although a large 2010 YC seems present in the surveys from 2011-2013. Therefore the low indices seen in 2014 should be treated with caution and may be related to the uncertainty in the survey.

The Disko Bay gillnet survey: The gillnet survey in the Disko bay targets pre fishery recruits of Greenland halibut at lengths of 35-50 cm. Since the survey uses gillnets with narrow selection curves, there is little difference between the trends of the CPUE and NPUE indices (Fig. 2.5). The gillnet survey CPUE and NPUE indicated low levels of pre fishery recruits in 2006 and 2007, but returned to average levels in 2008. The survey CPUE and NPUE reached a record high in 2011, but was lower in 2013 and 2014. The 2012 survey was troubled with a defective gillnet section (60mm) and can be disregarded. The overall long-term stability in the gillnet survey could indicate a steady supply of pre-fishery recruits (35-50 cm) to the stock.

If comparing the gillnet NPUE (all sizes) to the trawl survey indices of Greenland halibut larger than 35 cm, the surveys seems to be correlated leading to increased credibility in the indices of both surveys (Fig. 2.5). In general, both surveys show large year to year variation, which could be due to shifts in the distribution of the stock in and out of areas that are not covered by the surveys. It seems unlikely that the years with large changes in the indices, indicate a proportional true change in the stock.

Longline surveys in Uummannaq and **Upernavik:** were conducted in 2014, but the trends are highly variable and no general conclusions can be drawn from these surveys in recent years.

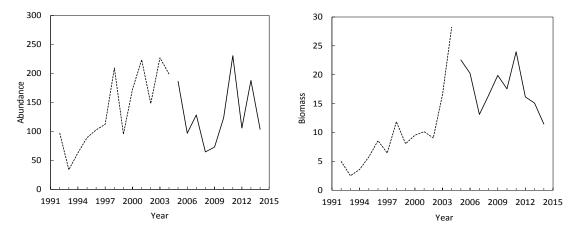

Fig 2.4. Greenland halibut in Div. 1A inshore: Disko Bay abundance and biomass indices in the Greenland Shrimp Fish trawl survey.

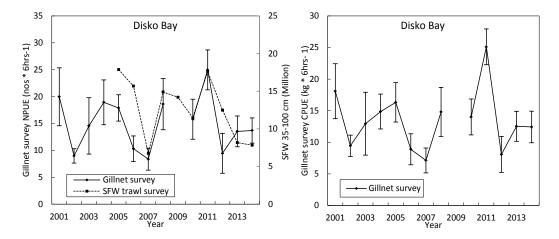

Fig. 2.5. Greenland halibut in Div. 1A inshore: Disko bay gillnet survey CPUE and NPUE + % CI indicated.

d) **Conclusion**:

Based on the available data there is nothing to indicate a change in the status of these stocks since the 2014 assessment.

These stocks will next be assessed in 2016.

3. Roundnose Grenadier (Coryphaenoides rupestris) in SAs 0 and 1

Interim Monitoring Report (SCR Doc. 15/03)

a) Introduction

There has been no directed fishery for roundnose grenadier in Subareas 0+1 since 1978. Since then roundnose grenadier has been taken as by-catch in the fishery for redfish and Greenland halibut. A total catch of 8 t was estimated for 2014. Catches of roundnose grenadier have been reported from inshore areas and Div. 1A where roundnose grenadier does not occur (13 t in 2014). These catches must be roughhead grenadier (*Macrourus berglax*) and were therefore excluded from totals for roundnose grenadier. It is also likely that catches from the offshore areas south of Divs. 0A-1A reported as roundnose grenadier may include roughead grenadier because their ranges overlap in these divisions.

	2006	2007	2008	2009	2010	2011	2012	2013	2014	2015
Agreed TAC	4.2									
Recommended TAC	ndf

ndf: No directed fishing. No TAC set for 2007 – 2015.

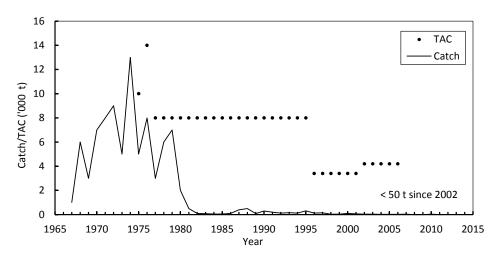

Fig. 3.1. Roundnose grenadier in Subareas 0+1: nominal catches and TACs. No TAC set for 2007-2015.

b) Data Overview

Research survey data i)

There has not been any survey that covers the entire area or the entire period. The various survey series available are not comparable. In the period 1987-1995, Japan in cooperation with Greenland has conducted bottom trawl research surveys in Subarea 1 covering depths down to 1 500 m. The survey area was restratified and the biomasses recalculated in 1997. Russia has in the period 1986-1992 conducted surveys covering Div. 0B and Divs. 1CD at depths down to 1 250 m until 1988 and down to 1 500 from then on. The surveys took place in October-November. During 1997-2014 Greenland conducted surveys in September -November covering Divs. 1CD at depths between 400 and 1500 m. Canada has conducted surveys in Div. 0B in 2000, 2001, 2011, 2013 and 2014 at depths down to 1 500 m. Furthermore, Canada and Greenland have conducted a number of surveys in Div. 0A and Div. 1A since 1999 but roundnose grenadier has very seldom been observed in those areas.

In the Greenland survey, the biomass index in Divs. 1CD increased gradually between 2010 and 2012, but in 2013 and 2014, returned to the very low levels seen during 2003-2008. During 2014, almost all the biomass was found in Div 1D. at depths of 600-1 400 m and the fish were generally small, between 4 and 9 cm pre anal fin length.

The Canadian surveys in Div. 0B in 2000 and 2001 also showed very low biomasses. The biomass was not calculated in 2011, 2013 and 2014 but few roundnose grenadiers were recorded.

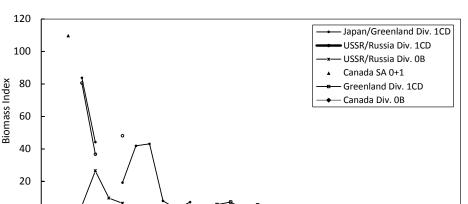

Fig. 3.2. Roundnose grenadier in Subareas 0+1: biomass estimates from Russian, Japan/ Greenland, Canadian and Greenland surveys in Div. 0B and Divs. 1CD.

2011

2014

c) Conclusion

0 L

Despite the lack of a directed fishery since 1978, the biomass of roundnose grenadier has remained at very low levels since 1999. In 2014, the biomass index was similarly low, and therefore, there is no reason to consider that the status of the stock has changed.

1999

Year

The next full assessment of this stock will take place in 2017.

4. Demersal Redfish (Sebastes spp.) in SA 1

Interim Monitoring Report (SCR Doc. 07/88, 15/03, 15/16, 15/Germany survey; SCS Doc. 15/Greenland)

a) Introduction

There are two demersal redfish species of commercial importance in subarea 1, golden redfish (*Sebastes marinus*) and demersal deep-sea redfish (*Sebastes mentella*). Relationships to other north Atlantic redfish stocks are unclear. Both redfish species are included in the catch statistics, since no historic species-specific data are available. Greenland operates the quota uptake by categorising the catches in three types of redfish: 1) fish caught by bottom trawl and longlines on the bottom are considered *Sebastes marinus*. 2), fish caught pelagic are considered *Sebastes mentella* and 3) fish caught as by-catch in the shrimp fishery are named *Sebastes sp*. From surveys operating both offshore and inshore in West Greenland it is known that the demersal redfish found on the shelf and in the fjords are a mixture of *S. marinus* and *S. mentella*.

b) Fisheries and Catches

The fishery targeting demersal redfish in SA1 increased during the 1950 from and peaked in 1962 at more than 60 000 t. Catches then decreased and have remained below 1000 t per year after 1986 with few exceptions. The differentiation between stocks in official statistics is however not straight forward. Even the correctness of the total landings of redfish from the area is uncertain. In 2014, 7 t were reported as by-catch in the shrimp fishery, 16 t were taken as by-catch in the offshore fishery targeting cod and Greenland halibut and 257 t were landed to factories, mostly as by-catches on small vessels operating inshore. Inshore catches are a mixture of commercially sized golden and deep-sea, mostly taken as a by-catch in the inshore fishery, targeting Greenland halibut and cod.

In 2014, an offshore trawler had landed 112 t to a factory in 1F, but only 11 t were actually caught in 1F. The rest was taken as by-catch in cod fishery in ICES XIV. The total reported catches were therefore 170 t in 2014 (Fig. 4.1). Sorting grids have been mandatory since October 2000, in order to reduce the amount of juvenile redfish taken as by-catch in the shrimp fisheries. Since 2012 sorting grids have also been used by shrimp vessels operating inshore (1AB). A study conducted in 2006 and 2007 indicated that redfish caught in the Greenland shrimp fishery are composed mainly of small redfish between 6 and 13 cm.

Recent catches ('000 t) are as follows:

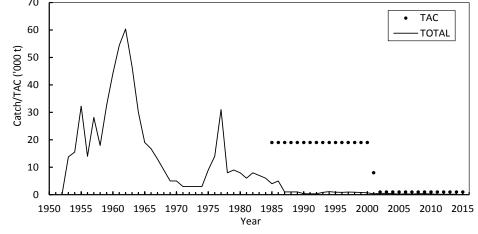

Fig. 4.1. Demersal redfish in Subarea 1: catches and TAC.

c) Data overview

i) Commercial fishery data

Mean length of golden redfish catches from sampling of EU-Germany commercial catches during 1962-90 revealed significant mean size reductions from 45 to 35 cm, with the most significant reductions occurring during the 1970s. There are no data available to estimate the size composition of catches of deep-sea redfish. Since redfish are mainly taken as by-catch no data of recent size composition in the landings are available.

ii) Research survey data

There are three recent surveys covering the demersal redfish stocks in Subarea 1; the EU-Germany survey (since 1982, 0-400m, 1B-F), the Greenland deep-water survey (since 1998, 400-1500m, 1CD) and the shallower Greenland Shrimp and Fish survey (since 1992, 0-600m, 1A-F). The latter has a more appropriate depth and geographical coverage in regards to redfish distribution, and covers the important recruitment areas in 1B. However, in this survey no separation of species were made prior to 2006 and the gear was changed in the Greenland Shrimp and Fish survey in 2005. Indices for redfish prior to 2005 have been converted to the new gear.

Golden redfish (*Sebastes marinus***).** The indices of the EU-Germany survey decreased in the 1980s and were at a very low level in the 1990s. The survey has revealed increasing biomass indices of Golden redfish (>17cm) since 2004 and the 2013 and 2014 indices are the highest observed since 1986 (Fig. 4.2). The biomass of golden redfish in the EU-Germany survey is however still far below the 1982 indices which must have been obtained from a stock below historic levels, since the size reduction in the landings occurred already during the 1970s.

The biomass index for golden redfish in the Greenland shrimp and fish survey increased in 2011 and 2012, but decreased slightly in 2013 and 2014. The general impression of the surveys is a slowly but steadily increasing biomass of Golden redfish.

Demersal deep-sea redfish (*Sebastes mentella***).**The indices of the EU-Germany survey have fluctuated without a trend throughout the time series (Fig. 4.3). The fluctuating trend is likely caused by poor survey

overlap with the depth distribution of adult deep-sea redfish. A joint Greenland-Japan deep-sea (1BCD) survey biomass index decreased from 1987 to 1995 (Fig. 4.3). The Greenland deep-water survey (1CD) indices were at a low level prior to 2007, but have gradually increased and the 2013 and 2014 indices are by far the highest observed. The biomass indices in the Greenland shrimp and fish survey also increased since 2007 (Fig. 4.3). The combined impression of these surveys is a steadily increasing biomass of deep-sea redfish (Fig. 4.3).

Juvenile redfish (both species combined). In the EU-Germany survey abundance indices of juvenile redfish (both species combined) has been at a very low level since 2001 (Fig. 4.4). The Greenland Shrimp and Fish survey covers the nursery areas in 1B and is dominated by redfish less than 20 cm. In this survey the abundance indices of both redfish species combined decreased gradually and particularly during the 1990s and the 2014 indices are the lowest observed (Fig. 4.4). Therefore, recruitment of juvenile redfish remains poor in the area and the increasing biomasses observed are likely a consequence of either increased survival of redfish and/or migration of redfish into subarea 1 from nearby areas.

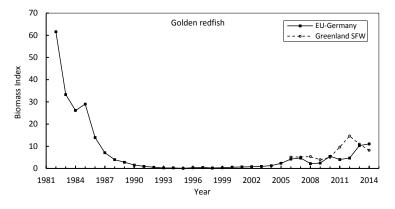

Fig. 4.2. Golden redfish (≥17 cm) survey biomass indices derived from the EU-Germany survey and the Greenland shrimp and fish survey (Divs. 1A-F) since 2006.

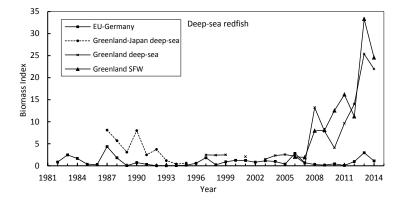

Fig. 4.3. Demersal deep-sea redfish (≥17 cm) survey biomass indices derived from the EU-Germany survey (1C-F), from the joint Greenland-Japan deep-sea survey (1987-1995), the Greenland deep-sea survey (1CD, 1997-2014) and the Greenland shrimp and fish survey.

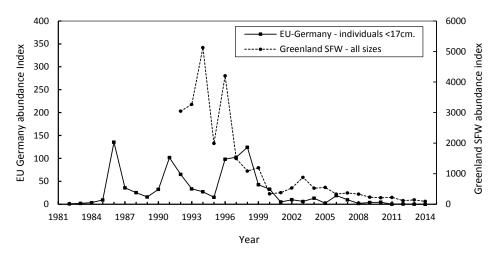

Fig. 4.4. Juvenile deep-sea redfish and golden redfish combined survey abundance indices for EU-Germany survey (1C-F, individuals <17cm) and the Greenland Shrimp and Fish survey (Divs. 1A-F, All sizes and both species combined).

d) Conclusion

Golden redfish

Although the surveys agree that the biomass of Golden redfish is increasing, the indices are still far below historic levels. The surveys also agree that recruitment is still failing in the area. Based on the available data there is no indication of any change in the status of these stocks since the most recent assessment.

Demersal deep-sea redfish

The surveys agree that the biomass of deep-sea redfish is increasing in the area. The surveys also agree that recruitment is still failing in the area. Based on the available data there is no indication of any change in the status of these stocks since the most recent assessment.

e) Research Recommendations

STACFIS reiterated the **recommendation** that the species composition and quantity of redfish discarded in the shrimp fishery in SA 1 be further investigated.

STATUS: No progress in 2015

This stock will next be assessed in 2017.

5. Other Finfish in SA 1

Before 2012, Denmark (on behalf of Greenland) requested advice for Atlantic wolffish, spotted wolffish, American plaice and thorny skate in subarea 1 under the term "other finfish". However, the requests of 2012 and 2013 no longer use this term, but strictly requests advice by species, and no longer requests advice for thorny skate. Therefore, the STACFIS report has been updated and advice for Atlantic wolffish, spotted wolffish and American plaice can now be found under their common names in section 5a and 5b.

5a. Wolffish in SA 1

Interim monitoring report (SCR Doc. 15/016; SCS Doc. 15-10)

a) Introduction

Three species of wolffish occur in Greenland waters: Atlantic wolffish (*Anarhichas lupus*), spotted wolffish (*Anarhichas minor*) and Northern wolffish (*Anarhichas denticulatus*). Only the two first are of commercial interest. Although spotted wolffish and Atlantic wolffish are easily distinguishable from one another, the fishing industry and catch statistics have so far made no distinction between the two species. Atlantic wolffish has a more southern distribution and seems more connected to the shallow offshore banks. Spotted wolffish

can be found in all divisions offshore and through survey and landing observations, but seems to be the dominant species in the fjords. The commercial fishery for wolffish in West Greenland increased during the 1950s and was originally based on the production of wolffish skins, but a production of frozen fillets started inshore in Div. 1C in 1951. Annual landings reached a level of more than 5 000 t by 1957 and stayed at a level of 4 000 to 6 000 until 1970. With the failing cod fishery off West Greenland, trawlers started targeting Atlantic wolffish on the banks off West Greenland and from 1974-1976 reported landings from trawlers were around 3 000 t per year. The highest reported catches occurred in 1977-1979, but in these years misreporting was documented. After 1980, the cod fishery gradually decreased in West Greenland and catches of wolffish also decreased during in this period. After 2002, increasing amounts were landed by small vessels operating inshore, indicating that the recent catches are mainly spotted wolfish. For spotted wolfish, Scientific Council in 2014 had recommended that all catches (including bycatch), should not increase beyond the 2009-13 average in 2015-17. For the Atlantic wolffish, SC recommended no directed fishing in 2015-2017 and bycatches in other fisheries be kept to the lowest possible level. To minimize by-catch in the shrimp fishery, offshore shrimp trawlers have been equipped with grid separators since 2002 and inshore shrimp trawlers since 2011. In 2014, 887 t of wolffish were landed to factories and 21 t were reported as by-catch in the offshore fishery targeting Greenland halibut, cod and shrimp.

ndf - No directed fishery

na – No advice

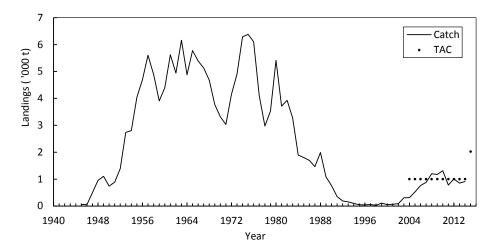

Fig. 5a.1. Wolffish in Subarea 1: Catches and TACs for Atlantic wolffish and spotted wolffish combined from 1945 to 2014.

b) Research survey data

There are two surveys partly covering the stocks of Atlantic wolffish and spotted wolffish in subarea 1. The EU Germany survey has a longer time series (since 1982, 1C-1F) and the Greenland shrimp and fish survey covers a larger geographical area (since 1992, 1A-F). The gear was changed in the Greenland shrimp and fish

survey in 2005, to a more modern trawl with rock-hopper gear. None of the surveys cover the inshore areas (except Disko Bay) and are unlikely to fully cover the distribution of either wolffish species.

Atlantic wolffish: Biomass indices decreased significantly in the 1980s in the EU-Germany survey (Fig. 5a.2). From 2002 to 2005 biomass indices increased to above average levels, but thereafter returned to the low levels observed during the 1990s. Abundance indices in the EU-Germany survey decreased after 1982, but were at a stable and perhaps slightly increasing level until 2005. After 2005 abundance indices in this survey decreased to below average levels, but remained stable after 2008 (Fig. 5a.2).

The Greenland shrimp and fish survey biomass indices were at low levels during the 1990s, but increased slightly from 2002 and until the gear change in 2004. After 2005, the surveys are highly correlated but the biomass index increases slightly more in the Greenland shrimp and fish survey than in the EU-Germany survey (Fig. 5a.2). Abundance indices in the Greenland shrimp and fish survey increased until the gear change in 2004. After 2005, the abundance indices in the two surveys seem correlated, but whereas the EU-Germany survey is stable the Greenland shrimp and fish survey increases slightly. The increasing abundance indices in the Greenland shrimp and therefore north of the EU-Germany survey area.

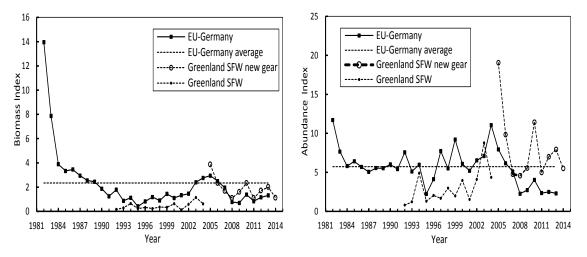

Fig. 5a.2. Atlantic wolffish in SA1: Survey biomass indices (left) and abundance indices (right) from the EU-Germany survey and the Greenland Shrimp and fish survey.

Spotted wolffish: Biomass indices decreased significantly in the 1980s in the EU-Germany survey and were at low levels during the 1990s (Fig. 5a.3). After 2003, survey biomass indices increased to the long term average and the 2013 indices are the highest observed since 1983. Abundance indices in the EU-Germany survey decreased from 1982 to 1995, but have increased since 2012 (Fig. 5a.3).

Biomass indices in the Greenland shrimp and fish survey were at low levels during the 1990s, but increased in 2003 and 2004. After the gear change in 2005, survey biomass indices have increased substantially (Fig. 5a.3). In the Greenland shrimp and fish survey, abundance indices have gradually increased throughout the time series (Fig. 5a.3).

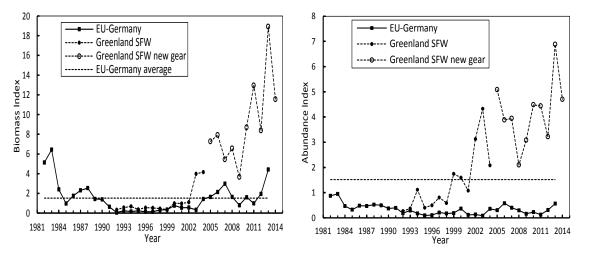

Fig. 5a.3. Spotted wolffish in Subarea 1: Survey biomass indices (left) and abundance indices (right) from the EU-Germany survey and the Greenland Shrimp and fish survey

c) Conclusion

Atlantic wolffish: The biomass is stable, but below average levels. The updated indices since the most recent assessment do not change the perception of the stock.

Spotted wolffish: Biomass indices have increased substantially in recent years and although the survey indices have decreased in 2014, the perception of the stock has not changed since the most recent assessment.

These stocks will next be assessed in 2017.

5b. American plaice (Hippoglossoides platessoides) in SA 1

(SCR Doc. 15/16; SCS Doc. 15-10)

a) Introduction

American plaice has been of very little commercial interest in Greenland at least for the past three decades. Occasionally, when the cod fishery was poor, vessels would turn to other species such as wolffish, redfish and American plaice on the banks off West Greenland. Reported catches of American plaice increased in the same years as wolffish were directly targeted, due to failing cod fisheries in the years after 1974. The highest reported catches occurred in 1977-1979, but in these years misreporting was documented. The catches of American plaice in these years are likely overestimated. Since then, American plaice in Subarea 1 have mainly been taken as a by-catch in fisheries targeting cod, redfish and shrimp and reported as unspecified by-catch. To reduce the number of juvenile fish discarded in the trawl fishery targeting shrimp, sorting grids have been mandatory since October 2000 (fully implemented offshore in 2002).

Recent catches ('000 t) are as follows:

	2005	2006	2007	2008	2009	2010	2011	2012	2013	2014
STATLANT 21	0	0	0	0	0	0	0	0	0	0
STACFIS	0	0	0	0	0	0	0	0	0	0

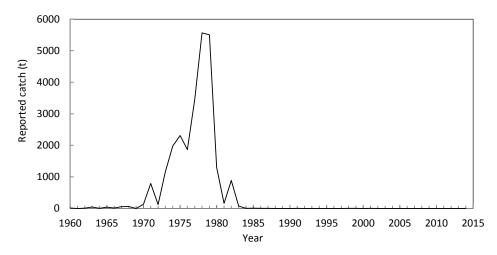

Fig. 5b.1. American plaice in Subarea 1: Reported catches of American plaice from SA1 from 1960 to 2014.

b) Research survey data

There are two surveys partly covering the American plaice stock in subarea 1. The EU-Germany survey has more shallow depth coverage (0-400m, Divs.1Bs-F), than the Greenland Shrimp Fish survey in West Greenland (0-600m, Divs. 1A-F).

Biomass indices decreased during the 1980s in the EU-Germany survey, but increased after 2002 to slightly above the series average. After 2004 the biomass indices decreased and stabilized at a low level.

The gear was changed in Greenland shrimp and fish survey in 2005 and calibration experiments indicated a length dependent calibration factor. The indices have not been converted to the new gear, making the two time series less comparable. The biomass indices in the Greenland Shrimp and fish survey steadily increased from 1992 to the gear change in 2004. After 2005 the indices have fluctuated without a clear trend (Fig. 5b.2).

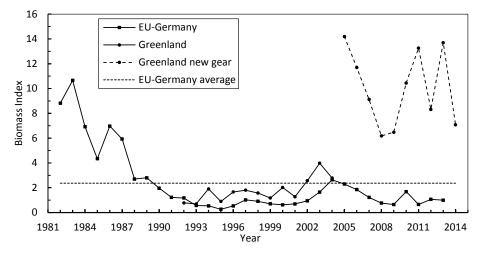

Fig. 5b.2. American plaice in Subarea 1: Biomass indices from the EU-Germany survey and the Greenland Shrimp and fish survey.

c) Conclusion

The biomass of the stock of American plaice in subarea 1 seems to be at a stable level, slightly higher than the 1990s, but far below the levels in the1980s. The updated indices do not change the perception of the stock since the most recent assessment.

d) Research Recommendation

STACFIS reiterated the **recommendation** that the species composition and quantity of American plaice discarded in the shrimp fishery in SA1 be further investigated.

STATUS: No progress

STACFIS reiterated the **recommendation** that the distribution of these species in relation to the main shrimpfishing grounds in SA1 be investigated, in order to further discover means of reducing the amount of discarded American plaice in the by-catch.

STATUS: No progress

This stock will next be assessed in 2017.

B. STOCKS ON THE FLEMISH CAP: SA 3 AND DIV. 3M

(SCR Docs. 15/10, 11, 13; SCS Doc. 15-08)

Recent Conditions in Ocean Climate and Lower Trophic Levels

• Ocean climate composite index for the Flemish Cap has trended downward since 2010 to a negative level in 2014 after 16 years of consecutive above average conditions.

• The composite spring bloom index in 3LM has shifted to negative levels in 2013-2014 after relatively high positive anomalies observed in previous 5 years.

• The composite zooplankton index has remained above normal since 2009 and reached its highest level in 2014.

• The composite trophic index increased to its highest level in 2014.

<u>. A. A</u>

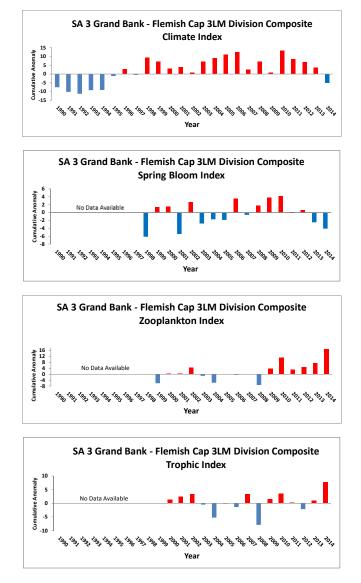

Fig. 16. Composite ocean climate index for NAFO Subarea 3 (Div. 3M) derived by summing the standardized anomalies during 1990-2014 (top panel), composite spring bloom (summed anomalies for the magnitude (integral during bloom) and peak intensity-amplitude metrics) index (Div. 3M) during 1998-2014 (2nd panel), composite zooplankton (sum of the four functional plankton taxa) index during 1999-2014 (3rd panel), and composite trophic (summed nutrient and standing stocks of phyto- and zooplankton indices) index (Divs. 3LM; note combined Division.) during 1999-2014 (bottom panel).

Environmental Overview

Water mass characteristics of the Flemish Cap area are derived from Labrador Current Slope Water and North Atlantic Current Water. The resulting mixture is generally warmer and saltier than the sub-polar Newfoundland Shelf waters with a temperature range of 3-4°C and salinities in the range of 34-34.85. The general circulation in the vicinity of the Flemish Cap consists of the offshore branch of the Labrador Current which flows through the Flemish Pass on the Grand Bank side and a jet that flows eastward north of the Cap and then southward east of the Cap. To the south, the Gulf Stream flows to the northeast to form the North Atlantic Current which influences waters around the southern areas of the Cap. In the absence of strong wind forcing the circulation over the central Flemish Cap is dominated by a topographically induced anti-cyclonic (clockwise) gyre. The stability of this circulation pattern may also influence the retention of ichthyoplankton on the bank which may influence year-class strength of various fish and invertebrate species. Variation in the abiotic environment is thought to influence the distribution and biological production of Newfoundland and Labrador Shelf and Slope waters, given the overlap between arctic, boreal, and temperate species. The elevated temperatures on the Cap compared to the Grand Banks may allow longer growing seasons and permit higher rates of productivity of fish and invertebrates on a physiological basis. The entrainment of North Atlantic Current water around the Flemish Cap, rich in inorganic dissolved nutrients generally supports higher primary and secondary production compared with the adjacent shelf waters.

141

Ocean Climate and Ecosystem Indicators

Ocean climate composite index on SA3 – Flemish Cap has trended downward since 2010 to a negative level in 2014 after 16 years of consecutive above average conditions. (Fig. 16). Surface temperatures on the Flemish Cap were below normal in 2014 by 0.6°C the lowest value since 1994. Bottom temperatures on the central Flemish Cap were also below normal by 0.5°C but remained above normal in waters generally deeper than 200 m.

The composite spring bloom index (Divs. 3LM) has declined in recent years (2013-2014) compared to positive anomalies observed throughout 2008 to 2012 (Fig. 16). Despite lower phytoplankton biomass, the composite zooplankton index (mainly composed of copepod and invertebrate plankton) reached a record-high level in 2014 and has remained at above normal levels since 2009 (Fig. 16). The composite tropic index which combines nutrient inventories and standing stocks of phytoplankton and zooplankton, increased to its highest level in 2014 (Fig. 16).

6. Cod (Gadus morhua) in Div. 3M

(SCR Docs. 15/33, 17; SCS Docs. 15-04, 05, 06, 07).

a) Introduction

i) Description of the fishery and catches

The cod fishery on Flemish Cap has traditionally been a directed fishery by Portuguese trawlers and gillnetters, Spanish pair-trawlers and Faroese longliners. Cod has also been taken as bycatch in the directed redfish fishery by Portuguese trawlers. Estimated bycatch in shrimp fisheries is low. Large numbers of small fish were caught by the trawl fishery in the past, particularly during 1992-1994. Catches since 1996 were very small compared with previous years.

From 1963 to 1979, the mean reported catch was 32 000 t, showing high variations between years. Reported catches declined after 1980, when a TAC of 13 000 t was established, but Scientific Council regularly expressed its concern about the reliability of some catches reported in the period since 1963, particularly those since 1980. Alternative estimates of the annual total catch since 1988 were made available in 1995 (Fig. 6.1), including non-reported catches and catches from non-Contracting Parties.

Catches exceeded the TAC from 1988 to 1994, but were below the TAC from 1995 to 1998. In 1999 the direct fishery was closed and catches were estimated in that year as 353 t, most of them taken by non-Contracting Parties according to Canadian Surveillance reports. Those fleets were not observed since 2000. Yearly bycatches between 2000 and 2005 were below 60 t, rising to 339 and 345 t in 2006 and 2007, respectively. In year 2008 and 2009 catches were increasing until 889 and 1 161 t, respectively. The fishery has been reopened in 2010 with a TAC of 5 500 t and a catch of 9 192 t was estimated by STACFIS. TAC of 10 000 t for 2011, 9 280 t for 2012, 14 113 t for 2013 and 14 521 t for 2014 were established. Since 2011, alternative estimates of the annual total catch have not been available. The inconsistency between the information available to produce catch figures used in the previous years assessments and that available for 2011-2014 has made impossible for STACFIS to provide the best assessments for some stocks. The assessment model of this stock was used to estimate the catches of 2011 and 2012, providing 13 650 t for 2011 and 13 380 t for 2012. In 2013, best available information for the catches of this stock is the Daily Catch Report data (see estimation of parameters), giving a total catch of 13 985 t. In 2014, several sources (STATLANT 21A (provisional for Faroe Islands) and DCR and for Faroe Islands, pers. comm.) resulted in an estimated STACFIS catch of 14 290 t. TAC for 2015 is 13 795 t.

	2006	2007	2008	2009	2010	2011	2012	2013	2014	2015

Recent TACs and catches ('000 t) are as follow:

ndf No directed fishery

¹ See estimation of parameters

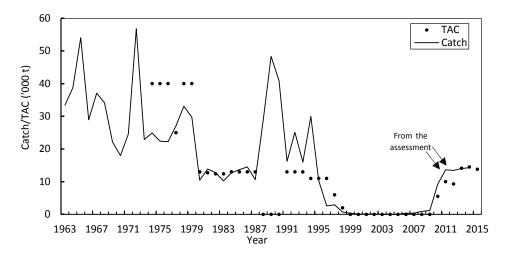

Fig. 6.1. Cod in Div. 3M: Catches and TACs. Catch line includes estimates of misreported catches from 1988 to 2010 and estimates from the model for 2011 and 2012. No direct fishery is plotted as 0 TAC.

b) Input Data

i) Commercial fishery data

Length and age compositions from the 2002 to 2005 commercial catches were not available. That information is available for the 1973 to 2001 period and for years 2006 to 2014. In 2010-2014, with the fishery open, there was a good sampling level. In 2014 there were length distributions from EU-Estonia, EU-Lithuania, EU-Portugal, EU-Spain, Faroe Islands (from trawls and from longliners) and Russia. The mode for EU-Estonia and EU-Spain was 52 cm. The EU-Lithuanian length distribution had a mode in 48 cm, and 50 cm the Faroes trawl one. Russia had the mode in 54 cm and Faroes longliner in 85 cm, much higher than for the rest of the countries. EU-Portugal had the smallest mode, at lengths between 39 and 42 cm. In 2014 there were inconsistencies in the aging of commercial catches, so the 2014 EU-survey Age-Length Key was used. In 2014 age 4 was the most abundant in the catch.

The mean length for the commercial length distribution shifted in last years from 54 cm between 2010 and 2012 to 42 cm in 2013. In 2014 there was a first mode at 51 cm and a second in the range of 39-42 cm. The Minimum Landing Size (MLS) for this stock is 41 cm. The shift to smaller sizes could be a concern as it would result in a larger number of individuals taken for the same TAC and additionally may result in an increase number of discards.

ii) Research survey data

Canadian survey. Canada conducted research vessel surveys on Flemish Cap from 1978-1985. Surveys were done with the R/V *Gadus Atlantica*, fishing with a lined *Engels* 145 otter trawl. The surveys were conducted in January-February of each year from 1978 to 1985 covered depths between130 and 728 m.

From a high value in 1978, a general decrease in abundance can be seen until 1985, reaching the lowest level in 1982 (Fig. 6.2).

Abundance at age indices were available from the Canadian survey. For this survey, indices of recruitment at age 1 were low in all the years except in 1982 and 1983 (Fig. 6.3).

EU survey. The EU Flemish Cap survey has been conducted since 1988 in summer with a Lofoten type gear. The survey indices showed a general decline in biomass going from a peak value in 1989 to the lowest observed level in 2003. Biomass index increased since then until 2012, especially from 2006. The growth of the strong year classes since 2005 has contributed to the increase in biomass. In 2013 a substantial decrease in biomass can be seen, reaching the level of 2010, although remaining at high level. In 2014 the biomass increased again reaching the maximum observed in the time series. Abundance has generally increased since 2005. The pattern, and difference between biomass and abundance, over 2011-2014 is driven by the very large 2010 and 2011 year classes (Fig. 6.2).

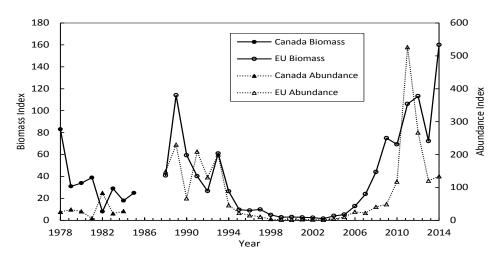

Fig. 6.2. Cod in Div. 3M: Survey abundance and biomass estimates from Canadian survey (1978-1985) and EU-Flemish Cap survey (1998-2014).

Abundance at age indices were available from the EU Flemish Cap survey. After several series of above average recruitments (age 1) during 1988-1992, the EU Flemish Cap survey indicates poor recruitments during 1996-2004, even obtaining observed zero values in 2002 and 2004. From 2005 to 2012 increased recruitments were observed. In particular, the age 1 index in 2011 is by far the largest in the EU series (Fig. 6.3; note that the level of both surveys is different in the two y-axis). In 2013 and 2014 the recruitment index dropped to the level at the beginning of the recovery of the stock.

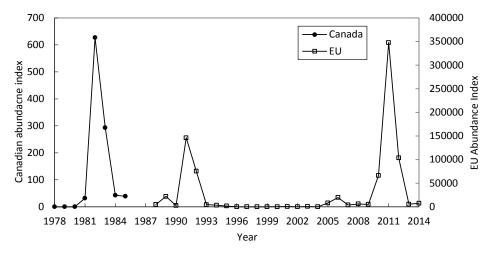

Fig. 6.3. Cod in Div. 3M: Number at age 1 in the Canadian survey (1978-1985) and EU survey (1988-2014).

Additional surveys have been conducted in Div. 3M but information was not available.

iii) Biological data

Mean weight at age in the stock, derived from the Canadian and the EU Flemish Cap surveys data, shows a strong increasing trend since the beginning of the series, although in the last years the mean weight shows a general decrease, mainly since 2009. For example the mean weight of a five year old cod has decreased from 3.9 kg in 2009 to 1.6 kg in 2014. Similar patterns have been observed across all ages.

There are maturity information from the Canadian survey for years 1978-1985 and for the EU survey for 1990-1998, 2001-2006 and 2008-2014. There was a continuous decline of the A_{50} (age at which 50% of fish are mature), going from above 5 years old in the late 1980s to just below 3 years old in 2002 and 2003. Since 2005 to 2011 there was an increase in the A_{50} , mostly in 2011, reaching in that year a value of 4.1 years old. In 2012 and 2013 the A_{50} decreased again to 3.4 years old in 2013 and increased in 2014 to the oldest age since 1994 (4.2 years old).

c) Estimation of Parameters

In 2008 onwards a VPA-type Bayesian model was used for the assessment of this stock. The input data for the model are:

Catch data: catch numbers and mean weight at age for 1988-2014, except for 2002-2005, for which only total catch is available. As STACFIS was unable to estimate the catch in 2011 and 2012 appropriately, a lognormal prior over these catches was set in the model with a median of 12 800 t and a 95% confidence interval of (9 905 t, 16 630 t). The value of the median is based on the 2010 STACFIS estimate raised by the ratio of 2011 over 2010 effort. In 2012, as the TAC is almost the same as the 2011 one and from the VMS data there is no evidence that the effort has changed, the same prior was used. SC decided to use total catches from the DCR in 2013 (13 985 t). This value was used again in the current assessment.

The STATLANT 21A was available for most of the countries fishing cod in 3M in 2014. For the countries with no STATLANT 21A available, the DCR was taken. In the case of Faroe Islands additional data were available during the meeting. A total of 14 290 tons of catch was set as the best available STACFIS catch to run the assessment.

Tuning: numbers at age from the Canadian survey (1978-1985) and from EU Flemish Cap survey (1988-2014).

Ages: from 1 to 8+ in both cases.

Catchability analysis: dependent on stock size for ages 1 to 2.

Natural Mortality: M was set via a lognormal prior as last year assessment.

Maturity ogives: Modelled using a Bayesian framework and estimating the years with missing data from the years with data.

Additional priors: for survivors at age at the end of the final assessment year, for survivors from the last true age in every year, for fishing mortalities at age and total catch weight for years without catch numbers at age, for numbers at age of the survey and for the natural mortality. Prior distributions were set as last year assessment.

The priors are defined as follows:

Input data	Prior Model	Prior Parameters
Total Catch	LN (median, sd)	Median=9.46, sd=0.1313
2011-2012		
Survivors(2014,a),	$LN\left(median = medrec \times e^{-medM - \sum_{age=1}^{a} medFsurv(age)}, cv = cvsurv \right)$	medrec=15000
a=1-6	LN median = medrec × e $_{age=1}$, $cv = cvsurv$	medFsurv(1,,7)={0.0001, 0.1, 0.5, 0.7, 0.7, 0.7,
Survivors(y,7),		0.7}
y=1988-2014		cvsurv=1
F(y,a), a=1-7,	LN(median = medF(a), cv = cvF)	medF=c(0.0001, 0.005, 0.01, 0.01, 0.01, 0.005, 0.005)
y=2002-2005		cvsurv=0.7
Total Catch	IN(motion CW (n) m mCW)	CW _{mod} is arised from the Baranov equation
2002-2005	$LN(median = CW_{mod}(y), cv = cvCW)$	cvCW=0.05
2002-2005		CVUW=0.05
Survey	$I(u) = IM\left(m_0 J_{ign} - u(u, g), g_{ij} - \sqrt{\frac{1}{g^{\psi(g)}}}\right)$	I is the survey abundance index
Indices: Canada and	$I(y) \sim LN\left(median = \mu(y, a), cv = \sqrt{e^{\frac{1}{ v '(a) }}} - 1\right)$	q is the survey catchability at age
EU (I)		N is the commercial abundance index
	$\mu(y,a) = q(a) \left(N(y,a) \frac{e^{-aZ(y,a)} - e^{-\beta Z(y,a)}}{(\beta - \alpha) Z(y,a)} \right)^{\gamma(a)}$	$\alpha = 0.5$, $\beta = 0.58$ for EU survey (survey made in
		July), and $\alpha = 0.08$, $\beta = 0.17$ for Canadian survey (made in January-February)
	$\gamma(a) \begin{cases} \sim N(\text{mean} = 1, \text{variance} = 0.25), & \text{if } a = 1, 2 \\ = 1, & \text{if } a \ge 3 \end{cases}$	Z is the total mortality
	$log(q(a)) \sim N(mean = 0, variance = 5)$	
	$\psi(a) \sim gamma(shape = 2, rate = 0.07)$	
М	$M \sim LN(\text{median}, cv)$	Median=0.218, cv=0.3

d) Assessment Results

The 2011 and 2012 catch posterior medians, estimated by the model, are 13 650 t and 13 380 t, respectively, similar to the values estimated in the last year's assessment.

Total Biomass and Abundance: Estimated total biomass and abundance show an increasing trend since the mid 2000s. Despite a slight decrease in biomass in the last year, the value is around the level of the early 1990s. Abundance has decreased over the last two years (Fig. 6.4).

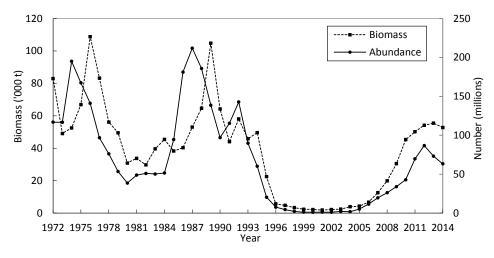

Fig. 6.4. Cod in Div. 3M: Biomass and Abundance estimates.

Spawning stock biomass: Estimated median SSB (Fig. 6.5) has increased since 2005 to the highest value of the time series and is now well above B_{lim} (14 000 t). This increase is due to several abundant year classes and their early maturity. Since the opening of the fishery in 2010, the SSB has remained at high levels.

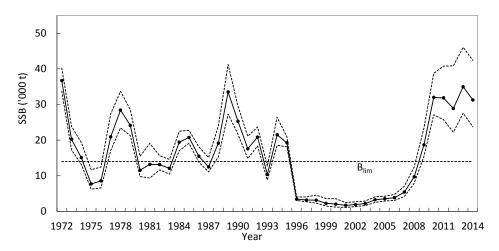

Fig. 6.5. Cod in Div. 3M: Median and 90% probability intervals SSB estimates. The horizontal dashed line is the *B*_{lim} level of 14 000 t.

Recruitment: After a series of recruitment failures between 1996 and 2004, values of recruitment at age 1 in 2005-2014 were higher, especially the 2011 and 2012 values although they have a high uncertainty. The last two years recruitments are much lower than the level observed in 2011-2012 (Fig. 6.6).

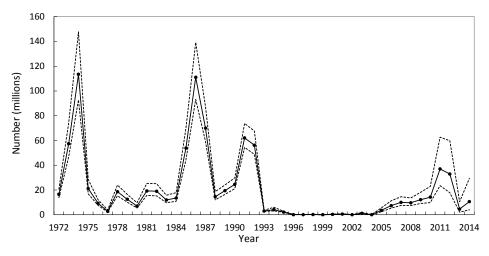

Fig. 6.6. Cod in Div. 3M: Recruitment (age 1) estimates and 90% probability.

Fishing mortality: *F* increased in 2010 with the opening of the fishery and it has remained stable since then at two times F_{lim} (0.131) and below historical average (0.495) (Fig. 6.7).

Consistent with the changing age distribution in the catches of 2010-2014, the exploitation patterns in the five years are different between them. In 2010, fishing mortality was relatively constant across ages 4-8+, but during 2011 the estimated fishing mortality on ages 6-8+ was much higher than on ages 3-5. In 2012 the largest values are ages 5-8+. In 2013 and 2014 it was at ages 7-8+ (Section g).

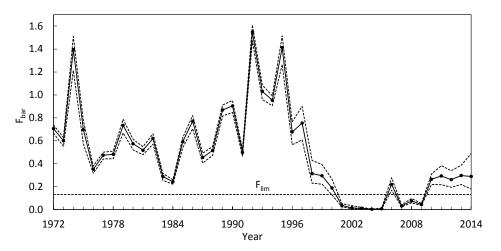

Fig. 6.7. Cod in Div. 3M: F_{bar} (ages 3-5) estimates and 90% probability intervals. The horizontal dashed line is the F_{lim} (0.131).

Natural mortality: The posterior median of *M* estimated by the model was 0.16, which is consistent with previous assessments.

e) Retrospective analysis

A six-year retrospective analysis with the Bayesian model was conducted by eliminating successive years of catch and survey data. Fig. 6.8 to 6.10 present the retrospective estimates for age 1 recruitment, SSB and F_{bar} at ages 3-5.

Retrospective analysis shows revisions in the recruitment and SSB, but no evident patterns can be seen (Fig. 6.8). *F* shows a general overestimation over the years (Fig. 6.9 and 6.10).

. A.A.

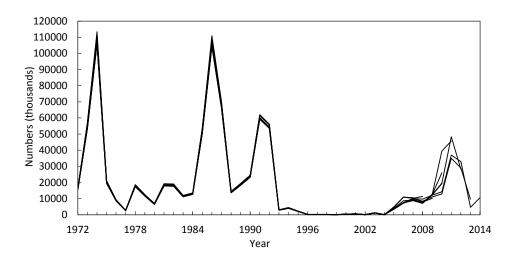

Fig. 6.8. Cod in Div. 3M: Retrospective results for recruitment.

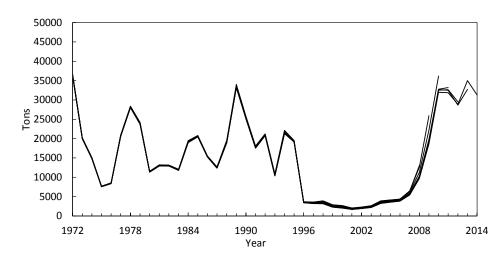

Fig. 6.9. Cod in Div. 3M: Retrospective results for SSB.

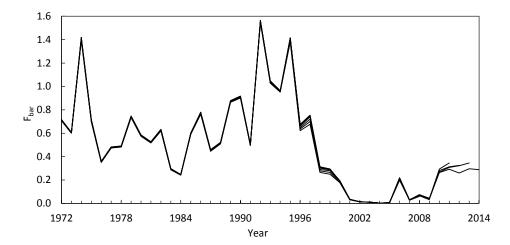

Fig. 6.10. Cod in Div. 3M: Retrospective results for average fishing mortality.

f) State of the stock

Current SSB is estimated to be well above B_{lim} . Recruitment has increased since 2005, especially in 2011 and 2012. The recruitment in 2013 and 2014 are much lower than the 2011-2012 values.

149

In 2010-2014, *F* has remained stable at a level more than twice F_{lim} .

g) Reference Points

STACFIS has previously estimated B_{lim} to be 14 000 t for this stock. SSB is well above B_{lim} in 2014. Fig. 6.11 shows a stock- F_{bar} plot. F_{lim} (0.131) for this stock is $F_{30\% SPR}$ (NAFO, 2014).

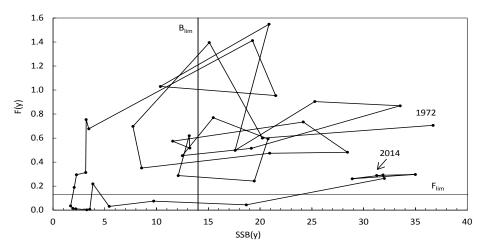

Fig. 6.11 Cod in Div. 3M: Stock- F_{bar} (3-5) (posterior medians) plot. B_{lim} and F_{lim} are plotted in the graph.

h) Stock projections

Stochastic projections of the stock dynamics from 2015 to 2018 were conducted. The variability in the input data is taken from the results of the Bayesian assessment. Input data for the projections are as follows:

Numbers aged 2 to 8+ in 2015: estimated from the assessment.

Recruitments for 2015-2018: Recruits per spawner were drawn randomly from 2010-2012. The 2013 value was omitted due to uncertainty in estimating the recruitment.

Maturity ogive for 2015-2018: Mean of the last three years (2012-2014) maturity ogive.

Natural mortality for 2015-2017: 2014 natural mortality from the assessment results.

Weight-at-age in stock and weight-at-age in catch for 2015-2018: Mean of the last three years (2012-2014) weights.

PR at age for 2015-2017: Mean of the last three years (2012-2014) PRs.

*F*_{bar}(ages 3-5): Four scenarios were considered:

(Scenario 1) $F_{bar}=F_{lim}$ (median value = 0.131).

(Scenario 2) $F_{bar}=3/4F_{lim}$ (median value = 0.098).

(Scenario 3) $F_{bar}=F_{statusquo}$ (median value = 0.285).

(Scenario 4) $F_{bar}=3/4F_{statusquo}$ (median value = 0.213).

All scenarios assumed that the Yield for 2015 is the established TAC (13 795 t). $F_{statusquo}$ was established as the mean fishing mortality over 2012-2014.

The results indicate that under all scenarios total biomass during the projected years have high probability of reaching levels near to the highest of all the 1972-2014 estimates (Fig. 6.12). In the case of the SSB, the levels are well above the highest of the assessed period in all the scenarios (Fig. 6.13). The removals associated with the F_{bar} based in $F_{statusquo}$ reach the level seen in 1992, before the collapse of the stock (Fig. 6.14).

A clear trend in the biological parameters of this stock in recent years has led to revisions in estimate numbers from one year assessment to the actual ones in the next assessment. If this pattern continues, the projection results could be biased.

Under all scenarios there is a very low probability (<1%) of SSB being below B_{lim} and for $F_{2012-2014}$ projections, a very high probability (>97%) of *F* exceeding F_{lim} .

	В		SSB		Yield	
	Median (9	90% CI)				
$F_{bar} = F$	Tlim (median	ı – 0.131)

The risk of each scenarios is presented in the following table, with the limit reference points for each case:

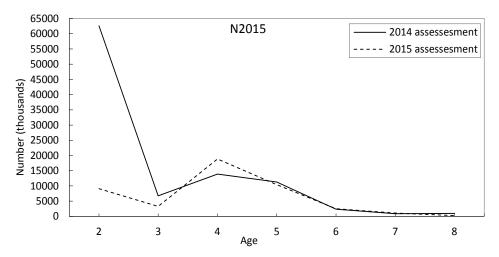

i) Research recommendations

STACFIS recommended that an age reader comparison exercise be conducted.

STATUS: No progress. This recommendation is reiterated.

STACFIS recommended that the most recent catch at age figures will revised.

STATUS: Comparison between numbers estimated for 2015 last year (with data until 2013 assessment) and numbers estimated for 2015 this year (with data until 2014 assessment, survivors) show us that no major changes occurred this year between both values for ages 3+. There is a big difference in age 2, due to the estimate on recruitment that last year was resampled for 2014.

The next full assessment for this stock will be in 2017.

7. Redfish (Sebastes mentella and Sebastes fasciatus) in Div. 3M

(SCR Docs. 15/17, 34; SCS Docs. 15-04, 05, 06, 07).

a) Introduction

There are three species of redfish that are commercially fished on Flemish Cap; deep-sea redfish (*Sebastes mentella*), golden redfish (*Sebastes marinus*) and Acadian redfish (*Sebastes fasciatus*). The term beaked redfish is used for *S. mentella* and *S. fasciatus* combined. Because of difficulties with identification and separation, all three species are reported together as 'redfish' in the commercial fishery. All stocks have both pelagic and demersal concentrations as well as a long recruitment process to the bottom, extending to lengths up to 30-32 cm. All redfish species are long lived with slow growth. Female sexual maturity is reached at a median length of 26.5 cm for Acadian redfish, 30.1 cm for deep-sea redfish and 33.8 cm for golden redfish.

i) Description of the fishery

The redfish fishery in Div. 3M increased from 20 000 t in 1985 to 81 000 t in 1990, falling continuously since then until 1998-1999, when a minimum catch around 1 100 t was recorded mostly as by-catch of the Greenland halibut fishery. An increase of the fishing effort directed to Div. 3M redfish is observed during the first years of the present decade, pursued by EU-Portugal and Russia fleets. A new golden redfish fishery

occurred on the Flemish Cap bank from September 2005 onwards on shallower depths above 300m, basically pursued by Portuguese bottom trawl and Russia pelagic trawl. Furthermore, the increase of cod catches and reopening of the Flemish Cap cod fishery in 2010 also contributed to the increase of redfish catch that was kept within 6 000-10 000 t between 2006 and 2014. Catch on 2013 and 2014 was stable at the lower limit of this recent interval, 6 771 t and 6 461 t respectively.

153

The new golden redfish fishery implied a revision of catch estimates, in order to split 2005-2014 redfish catch from the major fleets on Div. 3M into golden and beaked redfish catches. The estimated catch of beaked redfish in 2013 and 2014 were 5 168 t and 4 561 t respectively.

No STACFIS catch estimates were available for 2011-2014. Over the previous five years (2006-2010) an average annual bias of 15% plus was recorded between overall STACFIS catch estimate and overall STATLANT nominal catch. In order to mitigate the lack of scientific catch information a 15% surplus was added to the STATLANT catch of each fleet each year from 2011 onwards. These adjusted STATLANT catches are included in the present assessment as the STACFIS catch estimates.

	2006	2007	2008	2009	2010	2011	2012	2013	2014	2015
ТАС	5	5	5	8.5	10.0	10.0	6.5	6.5	6.5	6.7
STATLANT 21 A	6.3	5.6	7.9	8.7	8.5	9.7	6.7	6.8	6.5	
STACFIS Total Catch ^{1,2}	7.2	6.7	8.5	11.3	8.5	11.1	7.6	7.8	7.4	
STACFIS Catch ²	6.0	5.1	4.3	3.7	5.4	9.0	5.9	5.2	4.6	

Recent TACs, catches and by-catch ('000 t) are as follows:

¹Estimated redfish catch of all three redfish species.

²On 2011-2014 STACFIS catch estimates based on the average 2006-2010 bias.

³STACFIS beaked redfish catch

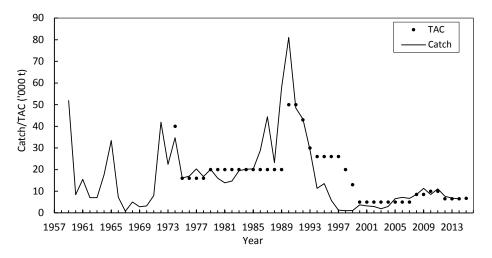

Fig. 7.1. Redfish in Div. 3M: total catches and TACs.

b) Input Data

The 3M redfish assessment is focused on beaked redfish, regarded as a management unit composed of two populations from two very similar species: the Flemish Cap *S.mentella* and *S.fasciatus*. The reason for this approach is the historical dominance of this group in the 3M redfish commercial catch. During the entire series of EU Flemish Cap surveys beaked redfish also represents the majority of redfish survey biomass (77%).

i) Commercial fishery and by-catch data

Sampling data. Most of the commercial sampling data available for the Div. 3M redfish stocks since 1989 are from the Portuguese fisheries. Length sampling data from Russia, Japan and Spain were also available for several years and used to estimate the length composition of the commercial catches for those fleets in those years. The annual length composition of the Portuguese trawl catch was applied to the rest of the commercial catches. The available 1998-2014 3M beaked redfish commercial length weight relationships from the Portuguese commercial catch were used to compute the mean weights of all commercial catches and corresponding catch numbers at length.

Redfish by-catch in numbers at length for the Div. 3M shrimp fishery is available for 1993-2004, based on data collected on Canadian and Norwegian vessels. No bycatch information has been available since 2005. The commercial and by-catch length frequencies were summed to establish the total removals at length. These were converted to removals at age using the *S.mentella* age-length keys with both sexes combined from the 1990-2014 EU surveys. Annual length weight relationships derived from Portuguese commercial catch were used for determination of mean weights-at-age.

The 1999-2007 cohorts dominated sequentially the overall catch through 2000-2014, some of them in several years, first in the shrimp by-catch and later on in the commercial fishery.

ii) Research survey data

EU Flemish Cap bottom trawl survey. Survey bottom biomass was calculated based on the abundance at length from EU bottom trawl survey for the period 1988-2014 and on the Div. 3M beaked redfish length weight relationships from EU survey data for the same period.

Age compositions for Div. 3M beaked redfish EU survey stock and mature female stock from 1989 to 2014 were obtained using the *S mentella* age length keys mentioned above. Mean weights-at-age were determined using the EU survey annual length weight relationships.

Gonads of the Flemish Cap beaked redfish species were collected by the EU survey since 1994, though not every year. Maturity ogives at length were primarily available from 1994 (*S.fasciatus* and *S.mentella*) and 1999 (*S.mentella*). New 2011 and 2014 maturity ogives were available for this assessment but the analysis of samples from the rest of the years backwards has not finished yet. Preliminary results revealed relevant changes on maturity for the three redfish species with length at maturity falling on all of them. The use on the most recent years of these new maturity ogives at length, instead of the former ones, would lead to a sudden increase on the size of the female spawning component of unrealistic high magnitude.

However the use of a knife edge female age 7 plus criteria to get a proxy of the beaked redfish mature female proportion at age, in place on last assessment, would generally inflate the number of female spawners at age throughout the whole assessment interval. So, in order to keep a conservative approach to spawning stock size, this assessment return to the former *S.mentella* and *S.fasciatus* maturity ogives at length to get the survey beaked redfish mature females at age, mature female proportions at age and female spawning stock biomass each year.

Survey results. The survey stock biomass and abundance declined from the first years of the survey until 1991, and were kept at low levels between 1991 and 2003. A sequence of above average year classes (2001-2005) coupled with high survival rates lead the stock and its exploitable part to a maximum in 2006. Year class strength declined afterwards, and the last cohort entering the exploitable stock (2010 year class in 2014) is the lowest recruitment at age 4. Until 2010 overall and exploitable stock follow similar trends to recruitment. Stock decline was halted on 2011 and on 2012 the stock showed signs of recovery, namely its exploitable part increased well above average. However biomass and abundance declined again on the last couple of years and on July 2014 were at or just below average. The spawning female survey indices extended their increase until 2009 but fall on 2010 and 2011. Those indices went up again on 2012 and are still staying well above average on 2014 (Fig. 7.2).

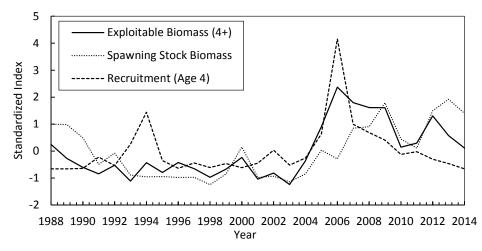

Fig. 7.2. Beaked redfish in Div. 3M: standardized biomass, female spawning biomass and recruitment at age abundance from EU surveys (1988-2014). Each series standardized to the mean and unit standard deviation.

This unexpected decline on all survey indices (but the ones related to the female spawning stock), can only be attributed to high mortality levels other than fishing mortality that over the past nine years were able to depress the stock size, from historical highs to the actual average level of the assessment interval. There is a strong possibility that recent higher levels on redfish natural mortality are associated to the increase of the Div. 3M cod stock from 2006 onwards.

Since 2004 a rapid increase was observed on survey biomass both of golden (*Sebastes marinus*) and Acadian (*Sebastes fasciatus*) redfish stocks. Due to their shallower depth distributions these two redfish species overlap with cod to an extent greater than deep sea redfish (*Sebastes mentella*). Since 2006, the cod stock started to recover, while those two redfish stocks declined sharply. Redfish is an important component in the diet of cod, especially on those years when abundant year classes enter successfully into redfish stocks.

c) **Estimation of Parameters**

The Extended Survivors Analysis (XSA) (Shepherd, 1999)⁵ was used to estimate stock size. The month of peak spawning (larval extrusion) for Div. 3M *S.mentella*, was taken to be February, and was used for the estimate of the proportion of fishing mortality and natural mortality before spawning. EU survey abundance at age was used for calibration. The XSA model specifications are given below:

Fleets	First	Last	First	Last
	year	year	age	age
EU summer survey (Div. 3M)	1989	2014	4	18
Tapered time weighting not applied			I	I
Catchability independent of stock size for all ag	es			
Catchability independent of age for all ages				
Terminal year survivor estimates not shrunk to	wards a mean F			
Oldest age survivor estimates not shrunk towar	rds the mean F of previou	us ages		
Minimum standard error for population estima	tes from each cohort age	= 0.5		

⁵ SHEPHERD, J. G. 1999. Extended survivors analysis: an improved method for the analysis of catch-at-age data and abundance indices. *ICES J. Mar. Sci.*, **56**(5): 584-591.

In years before 2006 natural mortality (*M*) remained at 0.1. The rational to select the best options for natural mortality between 2006 and 2012 are thoroughly explained in the sensitivity analysis sections of last assessments. A natural mortality of 0.4 was adopted for ages 4-6 through 2006-2010 interval, extended to all ages in 2009-2010. Since then natural mortality was assumed to be a time dependent/age independent parameter and on 2011-2012 declined to 0.125, a level much closer to what is usually considered the magnitude of natural mortality on redfish stocks (0.1).

Under such scenario one should expect that during the last nine years in general, and on 2013-2014 in particular

M may vary but should continue to be above 0.1, *F* should be below to well below *M*, and therefore the closer is the relation between survey and total abundance at age the better is the fit of natural mortality, the major component within total mortality that is driven abundance at each age since 2006.

On the sensitivity analysis of the present assessment eleven options regarding 2013-2014 natural mortality have been considered, from 0.1 to 0.4, with a closer look to the 0.1-0.2 interval. A set of eleven XSA runs have been performed and labelled according to the natural mortality adopted on each run on the last couple of years:

Each XSA 2015 run	M0.1	M0.125	M0.13	M0.14	M0.15	M0.16	M0.17	M0.18	M0.20	M0.30	M0.40
With a 2012-14 M option	0.1	0.125	0.13	0.14	0.15	0.16	0.17	0.18	0.2	0.3	0.4

All XSA 2015 runs

M = 0.4 on ages 4 – 6 in 2006 – 2008, and on all age groups in 2009 – 2010 M = 0.125 on all age groups in 2011 – 2012 (XSA 2013 assessment framework)

M = constant on all age groups and between years in 2013 and 2014

The purpose of the sensitivity analysis on the diagnostics is to select a M candidate that will allow a better fit of the model and also optimize the model performance. The goodness of fit of the model to survey data is measured by relative 1) Lower sum of squared *log* q_{age} residuals for 2013-2014 (for which a "best" *M* option is needed); 2) Lower sum of squared *log* q_{age} residuals extended to 2006-2014 (since the beginning of *M* increase by increasing cod predation);3) Higher correlations between exploitable (4+) survey abundance and XSA abundance over 2006-2014.

In the event of a tie between *M* candidates each of the three criteria has an importance according to the order of their presentation above.

	Run										
1 st Step Diagnostics	M0.1	M0.12 5	M0.13	M0.14	M0.15	M0.16	M0.17	M0.18	M0.20	M0.30	M0.40
SS log q residuals 2013-14	4.870	4.838	4.844	4.800	4.796	4.800	4.811	4.821	4.817	5.070	5.656
SS log q residuals 2006-14	50.95 3	50.807	50.78 9	50.80 1	50.79 8	50.80 1	50.82 8	50.80 8	50.91 0	51.35 3	52.28 6
XSA4+abundance vs Survey4+abundanc e r ²	0.612	0.606	0.605	0.603	0.600	0.597	0.595	0.592	0.586	0.556	0.522

Diagnostics results for this set of runs are shown below under a traffic light format.

A minimum *SS* log q_{age} residuals plateau is found for *M* between 0.14 and 0.16, regardless the time interval considered. This best range of natural mortalities also outputs "intermediate" correlations between 2006-2014 survey and XSA abundances that are closer to the green region of this diagnostic (Fig.'s 7.3). M0.13 run has been discarded taking into account its 2nd and 3rd rate green diagnostics compared with 1st and 2nd rate diagnostics of M0.14 to M0.16.

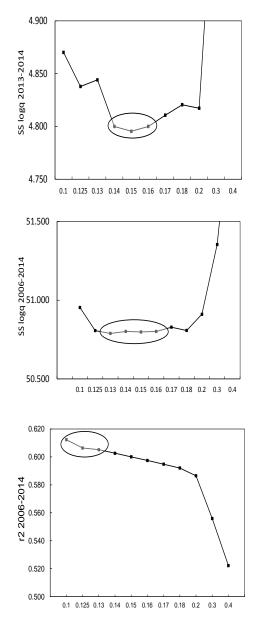

Fig. 7.3. Beaked redfish in Div. 3M: goodness of fit diagnostics of XSA₂₀₁₅ for several 2013-2014 *M* options (M0).

An option for a particular value of M between 0.14 and 0.16 could be justified by a clear improvement on the model performance leading to much more robust results and if so to much more consistent further projections. When looking at the other diagnostics from the corresponding three XSA₂₀₁₅ runs they are virtually the same and so no improvement can be anticipated by picking up either of those M's. Taking into account the above traffic light frame, low values at the left of the M green zone had a better diagnostics outlook than the higher ones at the right. So it is fair to conclude the lower boundary of the "best 2013-2014 natural mortality" interval is the M option more in line with the qualitative evaluation of the traffic light of 0.14 on 2013 and 2014.

On the present sensitivity analysis a final run, already with the newly selected 2006-2014 *M* frame was performed with the first age of independent catchability one year younger (at age 16). Main diagnostics and trajectories were compared to the former run, with age 17 as the start of age independent catchability.

Increasing the independent catchability range by starting at the previous younger age will speed the way to convergence by an important decline from 52 to 34 iterations, with opposite (but discrete) signals as regards the diagnostics used in the sensitive analysis. Mean catchabilities at age shown slight increases that turn into minimal increases in fishing mortality and minimal declines in abundance and biomass. In overall terms having age 16 as the start of the age independent catchability interval result on a slightly more conservative picture of the stock given by a more robust assessment, and so this option was adopted in the 2015 XSA framework.

d) Assessment Results

The 2015 XSA diagnostics kept the main features from past assessments: high variability associated with mean catchabilities and survivors, namely at younger ages, together with a familiar patchwork of *log q@age* residuals that remains with only small changes from its predecessors.

A 2015-2011 retrospective XSA was carried out (Fig 7.4). As regards exploitable biomass the retrospective XSA show no clear retrospective pattern, being the present assessment very much in line with their immediate predecessors. Reverse retrospective patterns are observed on the female spawning biomass (under estimate) and average fishing mortality (over estimate) but with small associated biases, even for recent years. Recruitment at age 4 of the most abundant year class (2002 year class in 2006) has been clearly over estimated on previous assessments.

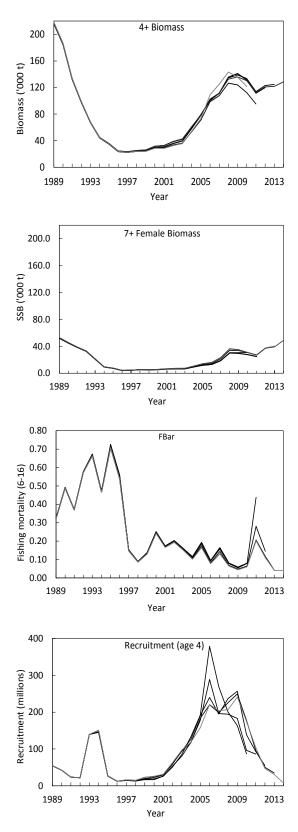

Fig. 7.4. Beaked redfish in Div. 3M: XSA retrospective analysis, last year 2014-2010: exploitable 4+ biomass, 7+ female biomass and average fishing mortality (ages 6-16).

Taking into account both the outcome of the sensitivity analysis and the consistency of present assessment with the previous ones, the 2015 XSA assessment was accepted with the 2013-2014 increase in natural mortality previously defined.

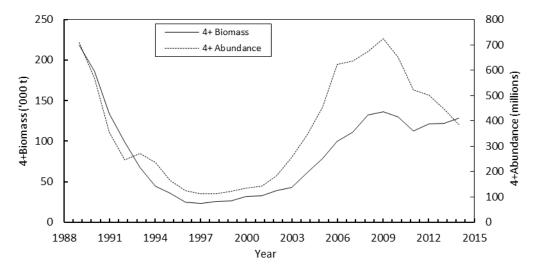

Fig. 7.5. Beaked redfish in Div. 3M: age 4+ biomass and Age 4+ abundance from XSA.

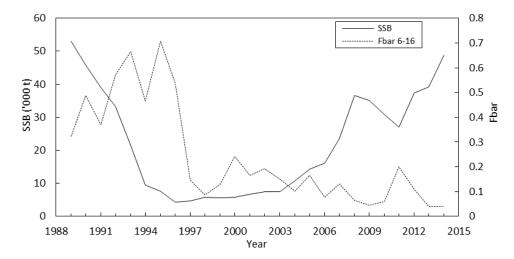

Fig. 7.6. Beaked redfish in Div. 3M: female spawning biomass and fishing mortality trends from XSA.

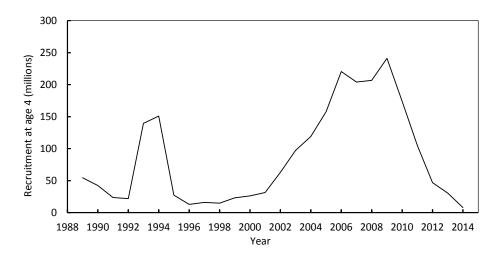

Fig. 7.7. Beaked redfish in Div. 3M: recruitment at age 4.

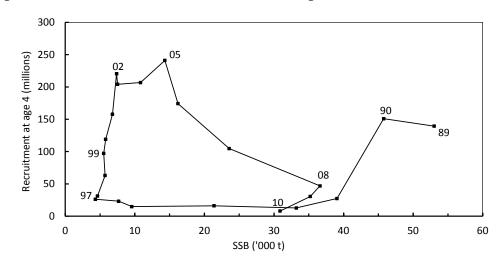

Fig. 7.8. Beaked redfish in Div. 3M: Stock/Recruitment plot (labels indicate age class).

Biomass and abundance (Fig. 7. 5): Experienced a steep decline from 1989 until 1996. The exploitable stock was kept at a low level until the early 2000s, basically dependent on the survival and growth of the existing cohorts. Above average year classes coupled with high survival rates allowed a rapid growth of biomass and abundance since 2003 and sustained the stock at a high level on 2008-2009. From 2009 onwards abundance went down being still on 2014 at a level well above the 1990's low. Biomass also declined but this trend was reversed by 2011-2012. Due to individual growth of survivors stock size in weight has improved on recent years and in 2013-2014 remains at high levels.

Spawning stock biomass (Fig. 7.6): Followed the trends of the exploitable stock until 2011. SSB is still increasing and in 2014 was well above the level that originated the high 2002-2006 recruitments.

Fishing Mortality (Fig. 7.7): High commercial catches (at a maximum level between 1989 and 1993) led to high fishing mortalities through the first half of the 1990's. Fishing mortality fell between 1996 and 1997 and since then has been kept at a low level until 2009. F increased in 2011 but returned to low level in 2013-2014.

Recruitment (Fig. 7.8 and 7.9): The recruitment increased from 2002 until 2006 and remained at a high level until 2009, with the 2005 year class as the most abundant of the assessment interval. Recruitment to exploitable stock declined continuously since then and is now at the level of the weak year classes from the 1990's. This decline may reflect higher natural mortalities at pre-recruited ages, rather than the return to a low productivity regime.

State of the stock: The stock has increased since 1996 and has remained at a relatively high level in recent years. Fishing mortality has remained stable at low level since the late 1990s. Recruitment has declined in the past five years.

e) Short term projections

Short term projections (2016-2017) were carried out for female spawning stock biomass (SSB) and catch under most recent level of natural mortality. Initial fishing mortality options were: 1) No fishing, $F_{0,2}$ Average 2012-2014 fishing mortality at age, $F@age_{2012-2014}$ and average 2013-2014 fishing mortality at age, $F@age_{2012-2014}$ and average 2013-2014 fishing mortality at age, $F@age_{2013-2014}$ 3) $F_{0.1}$ and F_{max} under current natural mortality of 0.14

Projections were initialized at the beginning of 2016 assuming *Catch statusquo@age* on the present year. Recruitment entering in 2015 was set at the 1989-2012 age 4 geometric mean. XSA survivors of each cohort were stepped forwards by the modified cohort's Pope Equation.

In order to get the updated $F_{0.1}$ and F_{max} a new yield per recruit analysis with M = 0.14 has to be performed, with all other inputs averaged from the whole interval where beaked redfish natural mortality exceeded 0.1 (2006-2014). Partial recruitment was assumed flat top at the last three (true) ages considered on the XSA, and a relative F @age 4-18 vector was given each year by the ratio of the F's @age to $Fbar_{16-18}$. The average relative F vector was the adopted the PR of this yield per recruit analysis. In order to reduce the weight of the plus group on the final results ages were virtually extended to age 29 with a plus group set at age 30. Mean weights and female maturity were kept constant and were the ones of the XSA 19 plus group.

As expected increasing natural mortality led to inflated fishing mortality reference points, with $F_{0.1}$ =0.2095 and F_{max} = 0.9250. Due to its unrealistic high magnitude as an *F* reference point candidate F_{max} was discarded from projections.

Short term stochastic projections of yield and female spawning stock biomass (SSB) under the four F options were initialized with abundance for ages 5 and older at the beginning of 2016. Being the internal and external standard errors from XSA diagnostics two measures of the uncertainty around the survivor estimate for each age, their average was adopted as the coefficients of variation of the starting population. Recruitment on 2016 and 2017 was fixed at the 1989-2012 geometric mean. Natural mortality was fixed at 0.14 for all ages and years. All other inputs at age are the last three year averages with associated errors at age.

Short term projections for female SSB (beginning 2018, 50th and 20th percentile) and average 2016-2017 yield (50^{th} percentile) under the selected *F* options and *M* at 0.14 are summarized on the table below.

SSB		F ₀	F ₂₀₁₂₋₂₀₁₄	F ₂₀₁₃₋₂₀₁₄	F _{0.1} Y	lield	F ₀	F ₂₀₁₂₋₂₀₁₄	F ₂₀₁₃₋₂₀₁₄	F _{0.1}
2018 _{50th %ile}		57675	51235	52879	48563 2	2016-2017 _{50th %ile}		6477	5345	8991
2018 _{20th %ile}		54201	48182	49732	45681 2	2015		4429	4429	4429
2014	48786				2	2014	4525			

From 50th percentile results all *F* options are suitable to pursue a management strategy that will keep SSB by the entry of 2018 at or above its present high level of 48 000t.

However year classes continuing to enter the projected exploitable biomass are increasingly weak. If a conservative forecast as regards near future recruitment fits better with recent observed past (20^{th} percentile), then keeping the actual low *F* on the next coming years is the precautionary option to sustain female SSB within its present high magnitude, even if the actual low recruitment regime prevails.

These projections are based in the assumption that natural mortality stay at its most recent level on 2015 and next coming years. Taking into account the uncertainty on the 2015-2017 level of natural mortality, and its impact on female spawning stock biomass at the end of the projection interval in relation with its size at the beginning (stability or reduction) for any of the fishing mortality options considered, these projections were not accepted as a basis for recommendations regarding 2016-2017 allowable catch for this stock.

f) Reference Points

There are no accepted limit reference points for this stock. Yield per recruit reference points are not considered candidate reference points for this stock due to variability in natural mortality.

g) Research Recommendations

STACFIS **recommends** that, in order to quantify the most likely redfish depletion by cod on Flemish Cap, and be able to have an assessment independent approach to the magnitude of such impact by species and to the size structure of the redfish most affected by cod predation, the existing feeding data from the past EU surveys be analyzed on a refined scale.

STACFIS also **recommends** that this important line of ecosystem research based on the feeding sampling routine of the EU survey catch be done on an annual basis.

The next full assessment for this stock is planned to be in 2017-8. American Plaice (*Hippoglossoides platessoides*) in Div. 3M

STACFIS **recommends** that work continue to investigate recent changes in natural mortality.

8. American plaice (Hippoglossoides platessoides) in Div. 3M

Interim Monitoring Report (SCR Doc. 15/17; SCS Docs. 15-04, 05, 06, 07)

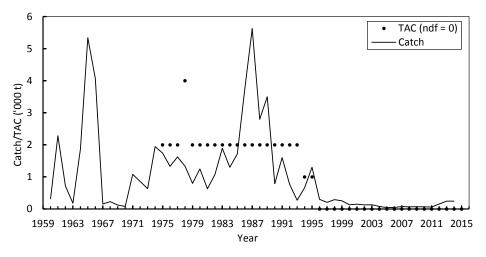

a) Introduction

A total catch of 145 t was reported for 2014 (Fig. 8.1).

Recent catches and TACs ('000 t) are as follows:

	2006	2007	2008	2009	2010	2011	2012	2013	2014	2015
Recommended TAC	ndf									
TAC	ndf									
STATLANT 21	0.1	0.1	0.1	0.1	0.1	0.1	0.2	0.2	0.2	
STACFIS	0.05	0.1	0.1	0.1	0.1	0.1	0.2	0.2	0.2	

ndf No directed fishing.

b) Data Overview

The EU bottom trawl survey on Flemish Cap was conducted during 2014. The survey estimates remained at low levels as previous years (Fig. 8.2 and 8.3).

All of the 1991 to 2005 year classes are estimated to be weak. Since 2006 the recruitment improved, particularly the 2006 year class.

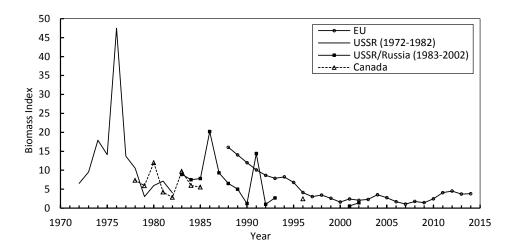

Fig. 8.2. American plaice in Div. 3M: trends in biomass index in the surveys.

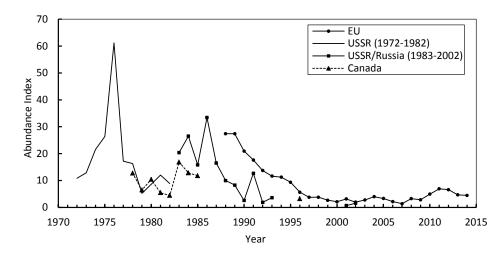

Fig. 8.3. American plaice in Div. 3M: trends in abundance index in the surveys.

c) Conclusion

Although the stock has increased slightly in recent years due to improved recruitment since 2009 (2006 Year-Class) it continues to be in a poor condition. Although the level of catches since 1996 is low, all the analysis indicates that this stock remains at a low level. There is no major change to the perception of the stock status.

The next full assessment is expected to be in 2017.

d) Research Recommendations

STACFIS **recommends** that several input frameworks be explored in both models (such as: q's; M (e.g. in relation to F0.1); ages dependent of the stock size; the proxies and its distribution in the VPA-type Bayesian model).

Due to the recent improved recruitment at low SSB, STACFIS **recommends** to *explore the Stock/Recruitment relationship and B*_{*lim*}.

STATUS: Work is been done but no progress to report. All recommendations will be address during the next full assessment

C. STOCKS ON THE GRAND BANK: SA 3 AND DIVS. 3LNO

(SCR Docs. 15/10, 11; SCS Doc. 15-08)

Recent Conditions in Ocean Climate and Lower Trophic Levels

• Ocean climate composite index on the Grand Bank transitioned to a weak negative value in 2014 after 16 consecutive years of above normal conditions, similar to the pattern observed on the Flemish Cap.

• The composite spring bloom index has returned to near normal in 2014 after negative anomalies observed in 2012-2013.

- The composite zooplankton index has remained above normal since 2009.
- The composite trophic index has remained near normal in recent years.

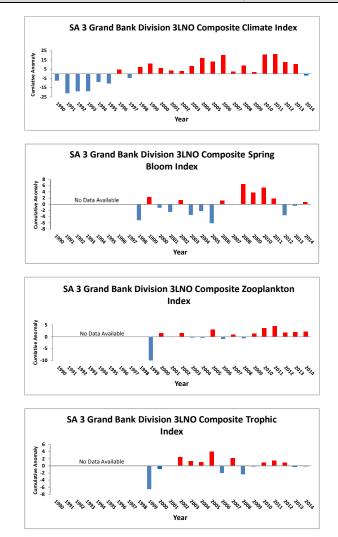

Fig. 17. Composite ocean climate index for NAFO Subarea 3 (SA3 Divs. 3LNO) derived by summing the standardized anomalies (top panel) during 1990-2014, composite spring bloom (summed anomalies for the magnitude (integral during bloom) and peak intensity-amplitude metrics) index (Divs. 3LNO) during 1998-2014 (2nd panel), composite zooplankton (summed functional plankton groups) index during 1999-2014 (3rd panel), and composite trophic (summed nutrient and standing stocks of phyto- and zooplankton indices) index (bottom panel) during 1999-2014.

. A A

Environmental Overview

The water mass characteristic of the Grand Bank are typical Cold-Intermediate-Layer (CIL) sub-polar waters which extend to the bottom in northern areas (3L) with average bottom temperatures generally <0°C during spring and through to autumn. The area of the winter-formed CIL water mass is a reliable index of ocean climate conditions in this area. Bottom temperatures range from 1-4°C in southern regions of 3NO due to atmospheric forcing and along the slopes of the banks below 200 m depth due to the presence of Labrador Slope Water. On the southern slopes of the Grand Bank in Div.°30 bottom temperatures may reach 4-8°C due to the influence of warm slope water from the south. The general circulation in this region consists of the relatively strong offshore Labrador Current at the shelf break and a considerably weaker branch near the coast in the Avalon Channel. Currents over the banks are very weak and the variability often exceeds the mean flow.

Ocean Climate and Ecosystem Indicators

Ocean climate composite index on the Grand Bank transitioned to a weak negative value in 2014 after 16 consecutive years of above normal conditions (Fig. 17). The annual surface temperatures at Station 27 in Div. 3L remained slightly above normal however bottom temperatures decreased to 0.6 SD below normal in 2014, the lowest since 1995. Vertically averaged temperatures decreased substantially since the peak in 2011 to slightly below normal in 2014. Surface and bottom salinities at Station 27 remained below the long term mean in 2014. The cold-intermediate layer (CIL; volume of < 0° C) in 2014 was at its highest level since 1985 on the Grand Bank during the spring. Spring bottom temperatures in Divs. 3LNO during the spring of 2014 were slightly below normal by -0.3° .

Standing stocks of phytoplankton based on the composite spring bloom index has remained near average in 2013-2014 (Fig. 17). Standing stocks of zooplankton based on the composite zooplankton index remain above normal since 2009 (Fig. 17). The composite trophic index also has also remained near normal in recent years (Fig. 17).

9. Cod (*Gadus morhua*) in Divs. 3NO

(SCR Docs. 15/07, 34; SCS Docs. 15/04, 05, 06, 07, 08, 09, 10)

a) Introduction

This stock has been under moratorium to directed fishing since February 1994. Since the moratorium catch increased from 170 t in 1995, peaked at about 4 800 t in 2003 and has been between 600 t and 1 100 t since that time. The catch in 2014 was 734 t.

	2006	2007	2008	2009	2010	2011	2012	2013	2014	2015
TAC	ndf									
STATLANT 21	0.3	0.7	0.7	0.6	0.8	0.8	0.7	1.1	0.7	
STACFIS	0.6	0.8	0.9	1.1	0.9	0.8	0.7	1.1	0.7	

Recent TACs and catches ('000 t) are as follows:

ndf: No directed fishery

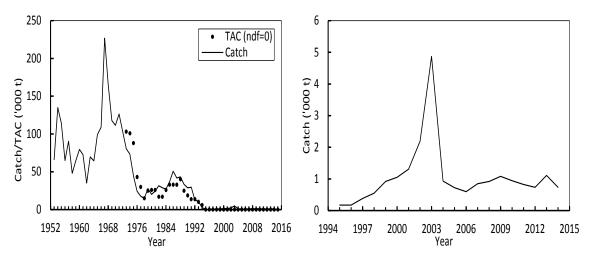

Fig. 9.1. Cod in Divs. 3NO: total catches and TACs. Panel at right highlights catches during the moratorium on directed fishing.

b) Data Overview

This assessment utilizes commercial catch at age data for 1959-2014 along with data from Canadian spring (1984-2014), autumn (1990-2013), and juvenile (1989-1994) surveys. As per previous assessments, trends in the EU-Spain survey were presented but not used as input to the assessment model.

i) Commercial fishery data

Catch-at-age. Calculation of catch at age used Canadian length and age sampling for 2013 and length sampling from Russia (2013-2014), EU-Portugal (2013-2014), EU-Spain (2013-2014) and EU-Estonia (2013). There was no Canadian length sampling available for 2014. The catch-at-age for these fleets was constructed by applying Canadian survey age length keys to the available length sampling. For various components there are no length and/or age sampling available, complicating the calculation of catch at age. The catch from 2013-2014 was dominated by ages 3-7.

ii) Research survey data

Canadian bottom trawl surveys. The spring survey biomass index declined from 1984 to its lowest level in 1995 (Fig. 9.2). Except for a brief period of improvement from 1998 to 2000 the index remained low to 2008. There was a substantial increase in 2009, the highest in the index since 1993. The index declined substantially in 2010 but has increased in the last three years. Trends in biomass are similar for the spring and autumn surveys and trends in abundance and biomass are similar except in the most recent years where biomass has been increasing and abundance has been stable (Fig. 9.2).

167

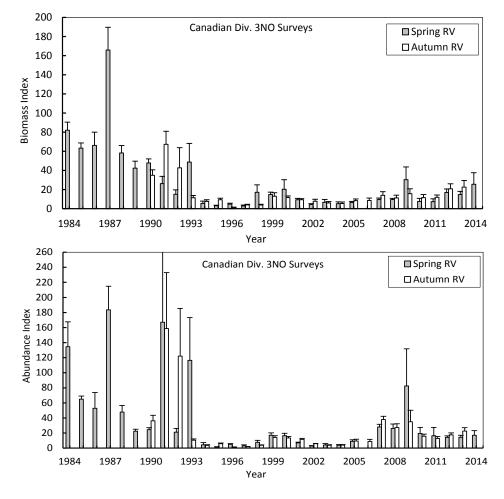

Fig. 9.2. Cod in Divs. 3NO: survey biomass and abundance indices from Canadian Spring and autumn surveys.

Canadian juvenile surveys. The index increased from 1989 to 1991, and declined steadily from 1992 to 1994 (Fig. 9.3).

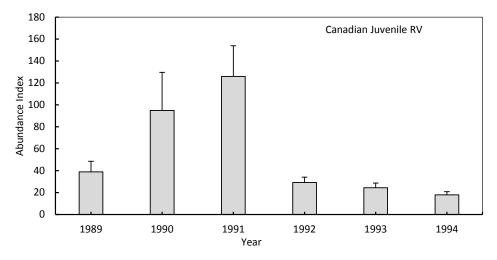

Fig. 9.3. Cod in Divs. 3NO: survey abundance index from Canadian juvenile surveys.

EU-Spain Divs. 3NO surveys. The biomass index was relatively low and stable from 1997-2005 with the exception of 1998 and 2001 (Fig. 9.4). There was a considerable increase in the index from 2008-2011, followed by a decline to 2013. In 2014 the index increased by more than three-fold to the highest value in the time series. Abundance and biomass indices show similar trends.

169

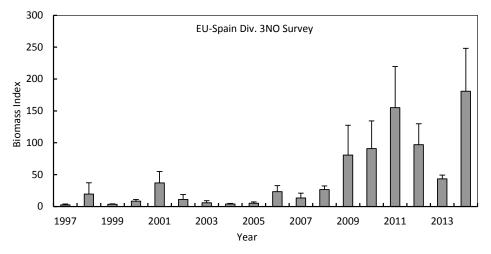

Fig. 9.4. Cod in Divs. 3NO: survey biomass index from EU-Spain Divs. 3NO surveys.

iii) Biological Studies

Maturity-at-age. Annual proportion mature is modeled by cohort. The estimated age at 50% maturity (A_{50}) ranged between 5.6 and 7.4 years for cohorts produced from the 1950s to 1980s. Age at 50% maturity declined for cohorts between 1980 and the late 1990s from approximately 6.8 to 4.5 years. Since that time there has been a variable but increasing trend in the A_{50} , with the most recent estimable cohorts (2006-2008) ranging from 5.2 to 6.4 years.

c) Estimation of Parameters

Sequential population analysis (SPA). An ADAPT was applied to catch-at-age calibrated with the Canadian spring, autumn and juvenile survey data (ages 2-10). The SPA formulation estimated numbers at ages 3-12 in 2015, age 12 from 1994-2014 and survey catchabilities at ages 2-10 for each survey. In the estimation, an *F*-constraint was applied to age 12 from 1959-93 by assuming that fishing mortality was equal to the average fishing mortality over ages 6-9. Natural mortality was assumed fixed at 0.2 for all years and ages. The mean square error of the model fit was 0.597.

d) Assessment Results

Biomass: The SPA results calibrated with the three Canadian survey indices indicate that the spawning stock was at an extremely low level in 1994 and remained stable at a low level to 2010. SSB has increased considerably over the past five years but the 2015 estimate of 38 454 t still represents only 64% of B_{lim} (60 000 t).

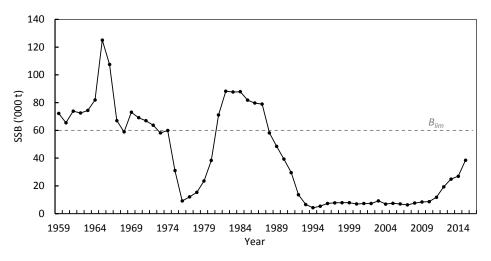

Fig. 9.5. Cod in Divs. 3NO: time trend of spawner stock biomass (SSB) from the SPA.

Recruitment: The 2005-2006 year classes were estimated to have the highest levels of recruitment in the past two decades, with levels comparable to those from the mid - late 1980s but well below historic values (Fig. 9.6). Estimated recruitment has not been as strong for subsequent year classes.

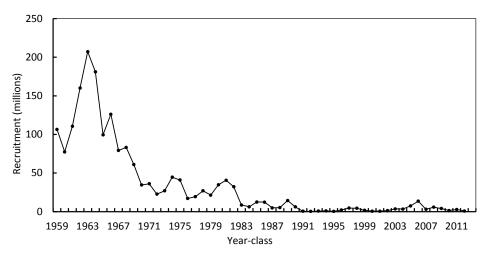

Fig. 9.6. Cod in Divs. 3NO: time trend of recruitment from the SPA.

Fishing mortality: Fishing mortality was low in the early years of the moratorium but then increased and peaked in 2003 (Fig. 9.7). Fishing mortality over the past seven years has been amongst the lowest values in the time series (<0.1) and well below F_{lim} .

170

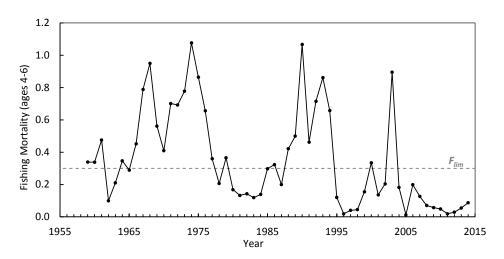

Fig. 9.7. Cod in Divs. 3NO: time trend of average fishing mortalities from the SPA.

e) State of the Stock

The spawning biomass has increased considerably over the past five years but the 2015 estimate of 38 454 t still represents only 64% of B_{lim} (60 000 t). This increase in biomass has been driven by the relatively strong 2005 and 2006 year classes and by fishing mortality values that are amongst the lowest in the time series (*F*<0.1) and well below F_{lim} (0.3). More recent year classes do not appear as strong and hence despite the low fishing mortality, the increasing trend in SSB may not persist beyond the short term.

f) Retrospective Analysis

A retrospective analysis was conducted to investigate whether there were systematic trends in the estimates of population size. A 5-year period was chosen to evaluate, whereby a complete year of data was removed in succession from the model but the formulation remained the same. Retrospective patterns were small, indicating consistency within the assessment (Fig. 9.8).

<u>, 64</u>

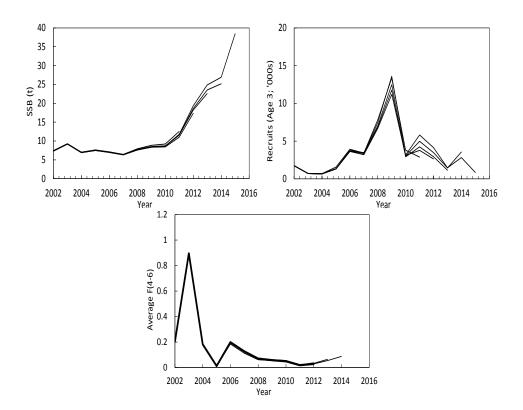

Fig. 9.8. Cod in Divs. 3NO: Five-year retrospective analysis of SSB, age 3 recruitment and average *F* on ages 4-6.

g) Reference Points

Mean fishing mortality for ages 4-6 in 2014 was estimated to be 0.09, well below the F_{lim} of 0.3 (Fig. 9.9). The current estimate of B_{lim} is 60 000 t, the point below which only poor recruitment has been observed. SSB in 2015 is estimated to be 38 454 t which is 64% of B_{lim} and above the level at which Fisheries Commission requested a detailed review of the limit reference point (FC Doc. 13/01). However, STACFIS notes that multiple stock-recruit points are required at SSB levels greater than 30 000 t prior to re-evaluation of this reference point as productivity at these levels of biomass is not well known.

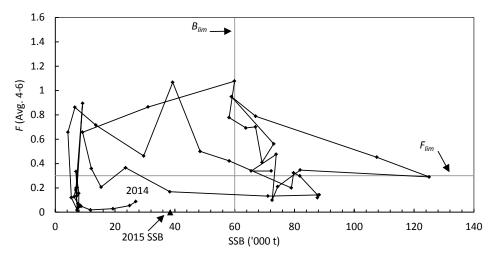

Fig. 9.9. Cod in Divs. 3NO: stock trajectory (1959-2014) within the NAFO PA framework.

h) Short-Term Considerations - Stochastic Projections

Simulations were carried out to examine the trajectory of the stock under two scenarios of fishing mortality: F=0, $F_{SQ}=0.057$ (the average F on ages 4-6 from 2012-2014). For these simulations the results of the SPA and the covariance of these population estimates were used. The following inputs were the basis of these projections:

Age	Estimate of 2015 population numbers ('000)	Relative error on population estimate	Weight-at-age mid-year (avg. 2012- 2014)	Weight-at-age beginning of year (avg. 2012- 2014)	Maturity-at- age (avg. 2012-2014)	PR rescaled relative to ages 4-6 (avg. 2012- 2014)
3	849.6	0.807	0.48	0.38	0.03	1.75
4	2138.4	0.486	0.75	0.61	0.11	1.73
5	724.6	0.435	1.16	0.89	0.38	0.83
6	1820.4	0.348	1.52	1.30	0.69	0.44
7	2233.7	0.294	2.04	1.80	0.84	0.50
8	945.4	0.274	2.85	2.67	0.96	0.38
9	3582.3	0.244	4.42	4.07	0.99	0.47
10	1606.7	0.231	6.41	5.79	1.00	0.50
11	499.3	0.241	7.41	6.47	1.00	0.38
12	368.4	0.246	10.73	8.61	1.00	0.00

Simulations were limited to a 3-year period. Recruitment (at age 3) was only re-sampled from the moratorium period (1994-2013) as this represents a reasonable expectation of what has occurred at recent low stock size levels.

At both F=0 and $F_{SQ}=0.057$ spawning stock biomass is estimated to increase and then decrease, with >99% probability that SSB will remain under B_{lim} by 2018 (Fig. 9.10, Table 1, Table 2). Also under both scenarios there is less than a 50% probability that the stock size at the end of the projection period (2018) will exceed the stock size at the start of the period (2015). If the fishing mortality in 2015-2018 remains at F_{SQ} (average for 2012-2014) then yield is projected to decline over the 3-year time period.

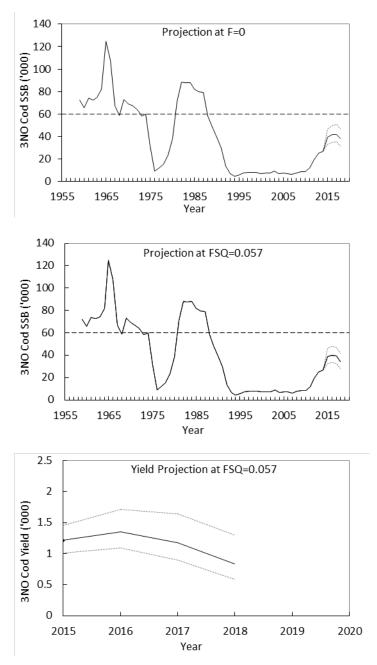

Fig 9.10. Cod in Divs. 3NO: Stochastic projections at F=0 and F=0.057 (the average F on ages 4-6 from 2012-2014). The solid line represents the median projected values and dashed lines are the 10th and 90th percentiles.

The next assessment of this stock will be in 2018.

i) Research Recommendations:

STACFIS **recommended** continuing to monitor the consistency in trends between the Canadian and EU-Spain surveys.

STATUS: Work is ongoing to examine the consistency among surveys and to explore the potential for including the EU-Spain survey as an input into the assessment model for Divs. 3NO cod.

STACFIS **recommends** investigating the potential use of a plus group in the assessment model.

10. Redfish (Sebastes mentella and Sebastes fasciatus) in Divs. 3L and 3N

Interim Monitoring Report (SCR Docs. 15/8, 20; 28 SCS Docs. 15/04, 05, 06, 07, 08)

a) Introduction

There are two species of redfish that have been commercially fished in Divs. 3LN, the deep-sea redfish *(Sebastes mentella)* and the Acadian redfish *(Sebastes fasciatus)*. The external characteristics are very similar, making them difficult to distinguish, and as a consequence they are reported collectively as "redfish" in the commercial fishery statistics and the surveys.

Catches declined to low levels in the early 1990s. From 1998-2009 a moratorium was in place. During that time catches were taken as by-catch primarily in Greenland halibut fisheries. With the reopening of the fishery in 2010 catches increased steadily, with removals of 6 300 t and 5 781 t in 2013 and 2014.

	2006	2007	2008	2009	2010	2011	2012	2013	2014	2015
ТАС	ndf	ndf	ndf	ndf	3.5	6.0	6.0	6.5	6.5	10.4
STATLANT 21	0.2	0.2	0.4	0.3	3.1	5.4	4.3	6.3	5.8	
STACFIS	0.5	1.7	0.6	1.1	4.1	5.4	4.3	6.3	5.8	

Recent nominal catches and TACs ('000 t) for redfish are as follows:

ndf: No directed fishing

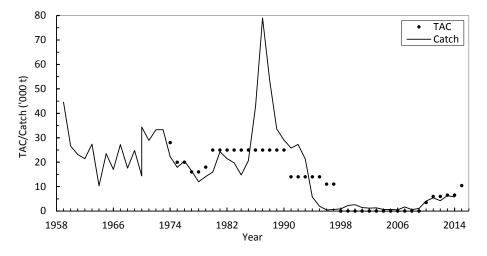

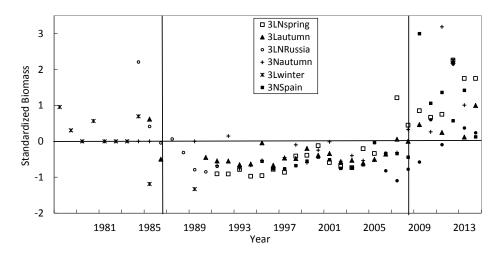

Fig. 10.1. 10.1. Redfish in Divs. 3LN: catches and TACs.

b) Data Overview

i) Research surveys

Most of the available surveys in Div. 3L and Div. 3N have been incorporated in the most recent assessment framework for this stock and have been standardized in order to be presented on Fig. 10.2. The Spanish survey series in Div. 3L, that so far has not been included in the analysis has also been standardized and presented.

177

Fig. 10.2. Redfish in Divs. 3LN: standardized survey biomass (1978-2014). Each series is standardized to the mean and unit standard deviation.

From the first half of the 1980s to the first half of the 1990s Canadian survey data in Div. 3L and Russian bottom trawl surveys in Divs. 3LN suggests that stock size suffered a substantial reduction. Redfish survey bottom biomass in Divs. 3LN remained well below average level until 1998 and started a discrete (but discontinuous) increase afterwards. A pronounced increase of the remaining biomass indices has been observed over the most recent years since 2006. Considering all available bottom trawl survey series occurring in Div. 3L and Div. 3N from 1978 until 2012, 100% of the biomass indices were at or above the average of their own series on 1978-1985, only 6% on 1986-2005, and 74% on 2006-2014.

c) Estimation of Stock Parameters

i) Relative exploitation

Ratios of catch to Canadian spring survey biomass were calculated for Div. 3L and Div. 3N combined and are considered a proxy of fishing mortality (Fig. 10.3). The spring survey series was chosen since is usually carried out on Div. 3L and Div. 3N during May until the beginning of June, and so can give an index of the average biomass at the middle of each year.

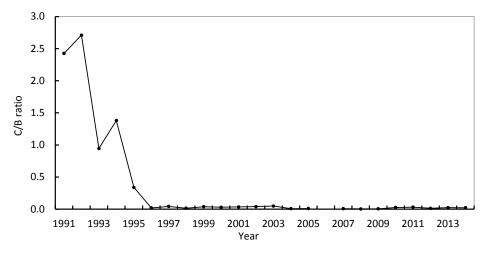

Fig. 10.3. Redfish in Divs. 3LN: C/B ratio using STACFIS catch and Canadian spring survey biomass (1991-2014).

Catch/Biomass ratio declined from 1991 to 1996, with a drop between 1992 and 1993. From 1996 onwards this proxy of fishing mortality is kept at a level close to zero.

d) Conclusions

There is nothing to indicate a change in the status of the stock. The increase of the catch with the reopening of the fishery in 2010, have not altered the perception of the stock given by the available surveys.

The next full assessment of this stock is planned for 2016.

11. American Plaice (Hippoglossoides platessoides) in Divs. 3LNO

Interim Monitoring Report (SCR Docs. 15/07, 09; SCS Docs. 15/04, 05, 06, 07, 08)

a) Introduction

American plaice supported large fisheries from the 1960s to the 1980s. However, due to the collapse of the stock in the early 1990s, there was no directed fishing in 1994 and a moratorium was put in place in 1995. In recent years American plaice is caught as bycatch mainly in trawl fisheries of yellowtail flounder, skate, Greenland halibut and redfish. After the moratorium, catches reached a peak in 2003, but have been lower since then (Fig. 11.1). Although there was new information presented on catch and effort, STACFIS was unable to continue using the effort method used to derive catch for 2014 without further investigation. Therefore it was agreed to consider catch estimation options during the next assessment. STATLANT 21A catch for 2014 was 1390 t. (Fig. 11.1).

	2006	2007	2008	2009	2010	2011	2012	2013	2014	2015
TAC	ndf									
STATLANT 21A	0.9	1.5	1.9	1.8	2.0	1.2	1.3	2.1	1.4	
STACFIS	2.8	3.6	2.5	3.0	2.9	2.7*	2.5*	3.3*	na	

Recent nominal catches and TACs ('000 t) are as follows:

ndf No directed fishing.

na Not available.

* Div. 3N Catch for 2011-2014 was derived using the following formula (NAFO, 2014):

Catch_y = (Effort_y/Effort₂₀₁₀)*Catch₂₀₁₀, for y = 2011, 2012, 2013.

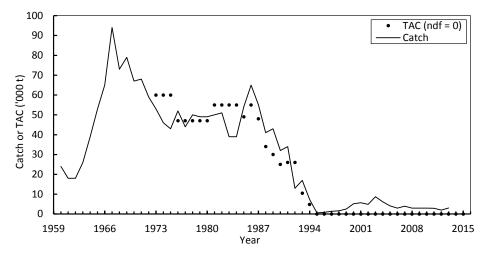

Fig. 11.1. American plaice in Divs. 3LNO: catches and TACs. No directed fishing is plotted as 0 TAC. There is no catch estimate for 2014.

b) Research Survey Data

Canadian stratified-random bottom trawl surveys. Biomass and abundance estimates from spring surveys for Divs. 3LNO declined during the late 1980s-early 1990s. Biomass estimates increased from 1996 to

2008 but declined in 2009 to levels of the late 1990s (Fig. 11.2). The biomass estimate has been increasing since 2009. The abundance index follows a similar trend.

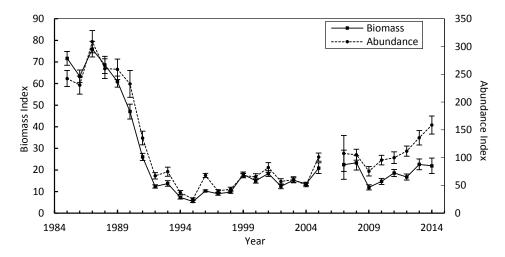

Fig. 11.2. American plaice in Divs. 3LNO: biomass and abundance indices from Canadian spring surveys (data prior to 1996 are Campelen equivalents and since then are Campelen).

Biomass and abundance indices from the autumn survey declined from 1990 to the mid-1990s. Divs. 3NO were not surveyed in 2014 and therefore survey results are not updated in the most recent year (Fig. 11.3). In Div. 3L biomass and abundance estimates are variable but have been generally increasing since 2009. Abundance has increased at a greater rate than biomass. Within Div. 3L, both biomass and abundance indices in 2014 are down slightly from the previous year.

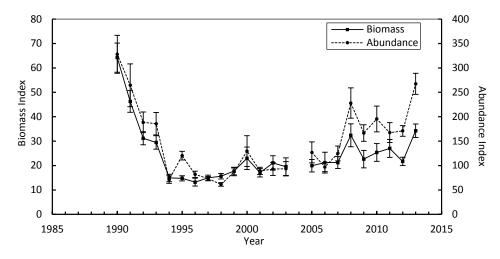

Fig. 11.3. American plaice in Divs. 3LNO: biomass and abundance indices from Canadian autumn surveys (data prior to 1995 are Campelen equivalents and since then are Campelen). No survey carried out in 2014 for Divs. 3NO.

EU-Spain Divs. 3NO Survey. From 1998-2014, surveys have been conducted annually by EU-Spain in the Regulatory Area in Divs. 3NO. The biomass and abundance indices varied without trend over the time series.

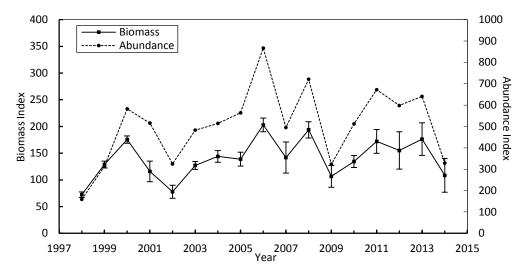

Fig. 11.4 American plaice in Divs. 3LNO: biomass and abundance indices from the survey by EU-Spain (data prior to 2001 are Campelen equivalents and since then are Campelen).

c) **Conclusion**

Based on available data, there is nothing to indicate a change in the status of the stock since the 2014 assessment.

The next full assessment of this stock is planned for 2016.

d) Research Recommendations

STACFIS **recommended** that investigations be undertaken to compare ages obtained by current and former Canadian age readers.

STATUS: Work is ongoing; it will be addressed during the next full assessment.

STACFIS **recommends** that investigations be undertaken to examine the retrospective pattern and take steps to improve the model.

STATUS: No progress on this recommendation; it will be addressed during the next full assessment.

12. Yellowtail flounder (Limanda ferruginea) in Divs. 3LNO

(SCR Docs. 15/08, 26; SCS Docs. 15/05, 06, 07, 08, 09)

a) Introduction

There was a moratorium on directed fishing from 1994 to 1997, and small catches were taken as by-catch in other fisheries. The fishery was re-opened in 1998 and catches increased from 4 400 t to 14 100 t in 2001 (Fig 12.1). Catches from 2001 to 2005 ranged from 11 000 t to 14 000 t. Since then, catches have been below the TAC and in some years, have been very low. The low catch in 2006 was due to corporate restructuring and a labour dispute in the Canadian fishing industry. Industry related factors continued to affect catches which remained well below the TAC since 2007. However, in 2013 and 2014, catches were higher at 10 700 t and 8 000 t, respectively.

	2006	2007	2008	2009	2010	2011	2012	2013	2014	2015
TAC ¹	15.0	15.5	15.5	17	17	17	17	17	17	17
STATLANT 21	0.6	4.4	11.3	5.5	9.1	5.2	3.1	10.7	8.0	
STACFIS	0.9	4.6	11.4	6.2	9.4	5.2	3.1	10.7	8.0	

Recent catches and TACs ('000 t) are as follows:

¹ SC recommended any TAC up to $85\% F_{msy}$ in 2009-2015.

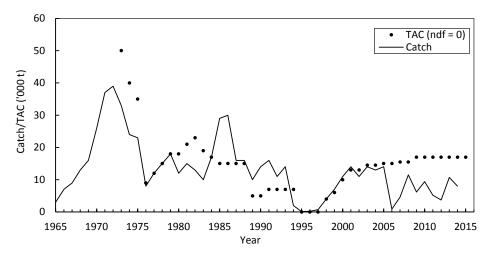

Fig. 12.1. Yellowtail flounder in Divs. 3LNO: catches and TACs. No directed fishing is plotted as 0 TAC.

b) Data Overview

i) Research survey data

Canadian stratified-random spring surveys. Although variable, the spring survey biomass index increased from 1995 to 1999 and since fluctuated at a high level.

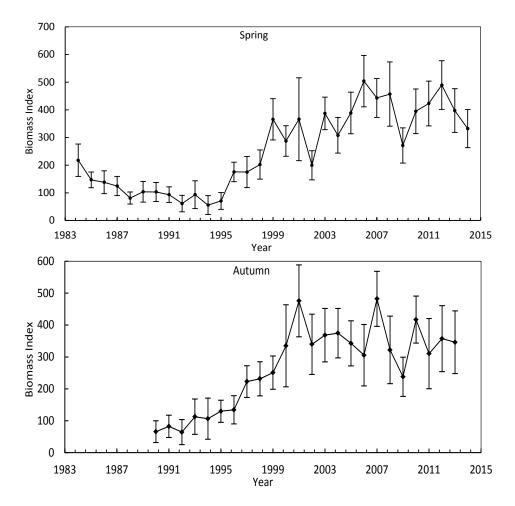

Fig.12.2. Yellowtail flounder in Divs. 3LNO: indices of biomass with approx 95% confidence intervals, from Canadian spring and autumn surveys. Values are Campelen units or, prior to autumn 1995, Campelen equivalent units. The 2014 Canadian autumn survey was incomplete.

Canadian stratified-random autumn surveys. The autumn survey biomass index for Divs. 3LNO increased steadily from the early-1990s to 2001, and although variable, it has remained relatively high since then (Fig. 12.2). The 2014 survey was incomplete due to problems with the research vessel.

EU-Spain stratified-random spring surveys in the NAFO Regulatory Area of Divs. 3NO. The biomass index of yellowtail flounder increased sharply up to 1999 and since remained relatively stable, even though the 2014 estimate is lower than the previous estimate (Fig. 12.3). Results are in general agreement with the Canadian series which covers the entire stock area.

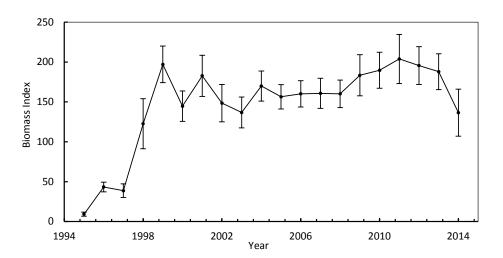

Fig.12.3. Yellowtail flounder in Divs. 3LNO: index of biomass from the EU-Spain spring surveys in the Regulatory Area of Divs. 3NO ±1SD. Values are Campelen units or, prior to 2001, Campelen equivalent units.

Stock distribution. In all surveys, yellowtail flounder were most abundant in Div. 3N, in strata on the Southeast Shoal and those immediately to the west (360, 361, 375 & 376), which straddle the Canadian 200 mile limit. Yellowtail flounder appeared to be more abundant in the Regulatory Area of Div. 3N in the 1999-2014 surveys than from 1984-1995, and the stock has continued to occupy the northern portion of its range in Div. 3L, similar to the mid-1980s when overall stock size was also relatively large. The vast majority of the stock is found in waters shallower than 93 m in both seasons.

c) Estimation of Parameters.

The previous assessment for this stock used a non-equilibrium surplus production model, ASPIC version 5.34. A major revision to the software (version7.02; Prager 2015) was examined using the previous assessment (2013) formulation in the new version to compare model estimates and fit criteria. No substantial differences in parameter estimation or model fit were noticed, and the current assessment proceeded with the most recent version of ASPIC. Model runs to explore other designations in the model (convergence criteria and penalty for B1>K) were also presented, and it was decided to proceed with the 2015 assessment using ASPIC version 7.02, with the recommended convergence criteria and with the penalty term for initial biomass being higher than the carrying capacity, K, set to 1. The input data for 2015 were: Catch data (1965-2014, with catch set to the average catch 2007-2014 (7 400t) in 2015), Russian spring surveys (1984-91), Canadian spring (Yankee) surveys (1971-82), Canadian spring (1984-2014 omitting 2006) surveys, Canadian autumn (1990-2013) surveys and the EU-Spain spring (1995-2014) surveys.

d) Assessment Results

Recruitment Total numbers of juveniles (<22 cm) from spring and autumn surveys by Canada and spring surveys by EU-Spain are given in Fig. 12.4 scaled to each series mean. High catches of juveniles seen in the autumn of 2004 and 2005 were not evident in either the Canadian or EU-Spain spring series. Although no clear trend in recruitment is evident, the number of small fish was above the 1996-2014 average in the Canadian surveys of 2010, and the 2011-2013 Canadian spring surveys. The spring survey by EU-Spain has shown lower than average numbers of small fish in the last eight surveys. Overall, recent recruitment appears to be lower than average.

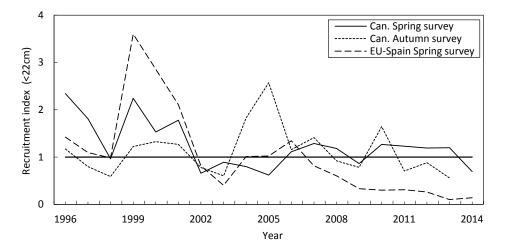

Fig.12.4. Yellowtail flounder in Divs. 3LNO: Juvenile abundance indices from spring and autumn surveys by Canada and spring surveys by EU-Spain. Each series is scaled to its mean (horizontal line).

Stock Production Model: The surplus production model results are very similar to the 2013 assessment results, and indicate that stock size increased rapidly after the moratorium in the mid-1990s and has leveled off. Bias-corrected estimates from the model suggests that a maximum sustainable yield (*MSY*) of 18 730 tons can be produced by total stock biomass of 72 500 tons (B_{msy}) at a fishing mortality rate (F_{msy}) of 0.26.

Biomass: Biomass estimates in all surveys have been relatively high since 2000. The analysis showed that relative population size (B/B_{msy}) was below 1.0 from 1973 to 1998. Relative biomass from the production model has been increasing since 1994, is estimated to be above the level of B_{msy} after 1999, and is 1.8 times B_{msy} in 2015 (Fig. 12.5).

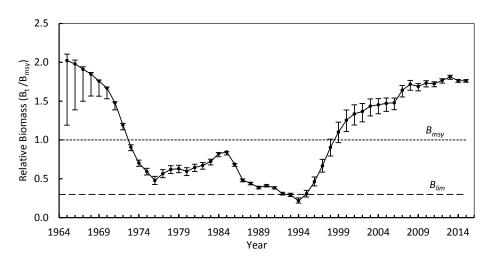

Fig. 12.5. Yellowtail flounder in Divs. 3LNO: bias corrected relative biomass trends with approximate 80% confidence intervals.

Fishing Mortality: Relative fishing mortality rate (F/F_{msy}) was above 1.0, in particular from the mid-1980s to early-1990s when the catches exceeded or doubled the recommended TACs (Fig. 12.6). *F* has been below F_{msy} since 1994. From 2007-2014 *F* averaged about 20% of F_{msy} .

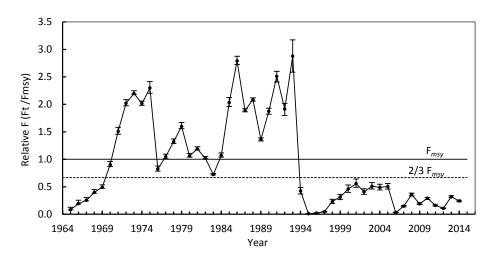

Fig. 12.6. Yellowtail flounder in Divs. 3LNO: bias corrected relative fishing mortality trends with approximate 80% confidence intervals.

e) State of the Stock

The stock size has steadily increased since 1994 and remains well above $B_{msy.}$ There is very low risk (<1%) of the stock being below B_{msy} or F being above $F_{msy.}$ Recent recruitment appears to be lower than average.

In most years since the moratorium (1994-97) was put in place, the catch remained below the estimated surplus production levels and have been low enough to allow the stock to grow (Fig. 12.7).

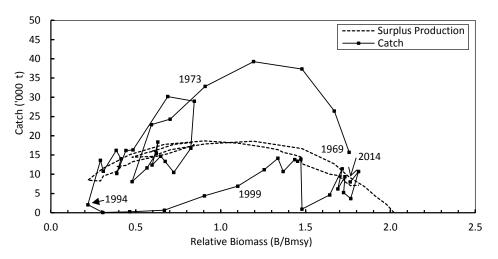

Fig. 12.7. Yellowtail flounder in Divs. 3LNO: catch trajectory.

f) Medium Term Considerations

Medium-term projections were carried out by extending the ASPIC bootstrap projections (1000 iterations) forward to the year 2018 assuming two levels of catch in 2015 (either TAC level (17 000t) or the average of the 2007-2014 catch (7 400 t)) followed by constant fishing mortality from 2016-2018 at several levels of *F* (2/3 F_{msy} , 75% F_{msy} , and 85% F_{msy} , and F_{msy}). The projections are conditional on the estimated values of r, the intrinsic rate of population growth and K, the carrying capacity.

 F_{msy} was estimated to be 0.26. Although yields are projected to decline in the medium term at both levels of catch in 2015 for 2/3 F_{msy} , 75% F_{msy} , and 85% F_{msy} (Table 12.1; Fig. 12.8), at the end of the projection period, the risk of biomass being below B_{msy} is less than 1% in all cases.

- The probability that $F > F_{msy}$ in 2016-2018 was less than .01 at 2/3 and 75% F_{msy} for both catch scenarios in 2015 (Table 12.2). At 85% F_{msy} , the probability that $F > F_{msy}$ was 0.05 in the medium term for both scenarios, and projected at the level of F_{msy} , the probability that $F > F_{msy}$ is approximately 0.5. For biomass projections, in all scenarios for 2013-2016, the probability of biomass being below B_{msy} was less than 0.01. Biomass in 2014 is projected to be greater than B_{2018} at all levels of F projected for both catch scenarios with probability >0.99.
- Table 12.1. Medium-term projections for yellowtail flounder. Estimates and 80% confidence interval for yield and relative biomass B/B_{msy} , are shown, for projected *F* values of 2/3 F_{msy} , 75% F_{msy} and 85% F_{msy} . The results are derived from ASPIC bootstrap runs (1000 iterations) with assumed catches in 2015 of 7 400 tons (mean catch 2007-2014) or 17 000 t(TAC in 2015).

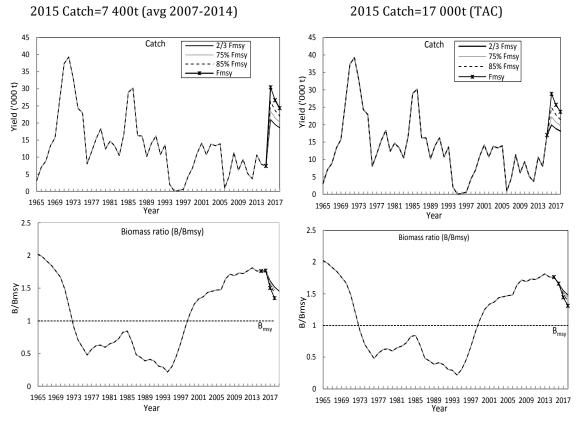

Fig. 12.8. Yellowtail flounder in Divs. 3LNO: stochastic projections from 2016-2018 at four levels of F (2/3 F_{msy} , 75% and 85% F_{msy} and F_{msy}) for two catch scenarios. Top panels show projected yield and lower panels are projected relative biomass ratios (B/B_{msy}). Results are median values derived from ASPIC bootstrap runs (1000 iterations).

g) Reference Points:

The stock is presently above B_{msy} and F is below F_{msy} (Fig. 12.9). Scientific Council considers that 30% B_{msy} is a suitable limit reference point (B_{lim}) for stocks where a production model is used. At present, the risk of the stock being below $B_{lim} = 30\% B_{msy}$ is very low (<1%).

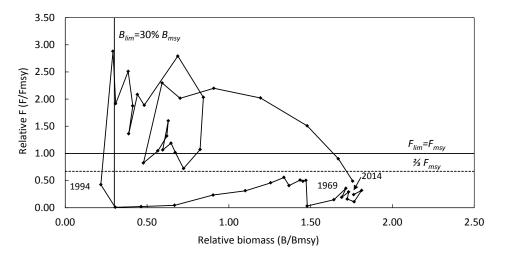

Fig. 12.9. Yellowtail flounder in Divs. 3LNO stock trajectory estimated in the surplus production analysis, under a precautionary approach framework.

Currently the biomass is estimated to be above B_{lim} and F, below F_{lim} (= F_{msy}) so the stock is in the safe zone as defined in the NAFO Precautionary Approach Framework.

The next full assessment of this stock will be in 2017.

h) Research recommendations

STACFIS **recommends** that further work be undertaken to better understand the uncertainties estimated in the ASPIC model.

13. Witch Flounder (Glyptocephalus cynoglossus) in Divs. 3NO

(SCR Docs. 15/37, 38; SCS Docs. 15/04, 05, 06, 07)

a) Introduction

ndf = no directed fishing

Reported catches in the period 1972-84 ranged from a low of about 2 400 t in 1980 and 1981 to a high of about 9 200 t in 1972 (Fig. 13.1). Catches increased to around 9 000 t in the mid-1980s but then declined steadily to less than 1200 t in 1994, when a moratorium was imposed on the stock. Since then, catches have averaged below 500 t; in 2014 the catch was estimated to be 335 t. The NAFO Fisheries Commission reintroduced a 1 000 t quota for 2015.

Recent catches and TACs ('000 t) of witch flounder in Divs. 3NO

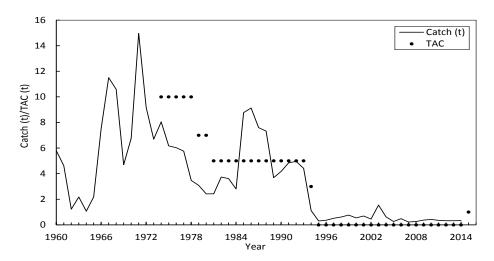

Fig. 13.1. Witch flounder in Divs. 3NO: catches and TAC. No directed fishing is plotted as 0 TAC. The fishery was reopened in 2015 with a TAC of 1 000 t.

b) Data Overview

i) Commercial fishery data

Catch and effort. There were no recent catch per unit effort data available.

Length frequencies. Length sampling was available from by-catches in directed fisheries for other species by EU-Spain, EU-Portugal, and Russia in 2014 (Fig. 13.2). The Spanish data (SCS Doc. 15/05), from Divs. 3NO G. halibut, redfish and skate fisheries, showed most of the witch flounder catch was between 30 and 44 cm in length, with a peak at 35 cm. In the Portuguese data (SCS 15/06) for Div. 3N lengths between 46 cm and 50 cm dominated the catch, with a mode at 46 cm (mean length of 49.4 cm) (Fig. 13.2). In Div. 30 the Portuguese catch was dominated by lengths between 28 cm and 38 cm, with a mode at 32 cm (mean length of 33.1 cm) (Fig. 13.2). For Russia (SCS Doc. 15-07), sampling of witch by-catch in Divs. 3NO showed the length of witch flounder ranged from 26 to 50 cm. Individuals from 32 to 44 cm in length made up the bulk of catches (Fig. 13.2). Russian sampling (SCS Doc. 15-07) of witch by-catch indicates a length range of 38-60 cm and mean length of 50.1 in Div. 3N and a length range of 30-40 cm with a mean length of 36.7 cm in Div. 30) (Fig. 13.2).

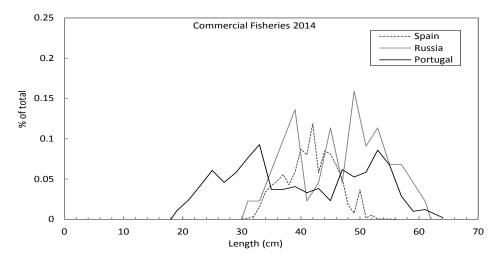

Fig. 13.2. Witch flounder length frequency (cm) distributions for EU-Spain, Russia, and EU-Portugal commercial fisheries in NAFO Divs. 3NO in 2014

ii) Research survey data

Canadian spring RV surveys. The Divs. 3NO estimate of biomass index, although variable, has shown a general decreasing trend from 1985 to 1998 followed by an increase from 1998 to 2003. From 2010 to 2013 the index increased to values near the series high from 1987, although the 2013 point estimate was imprecise. Biomass values in 2014 declined sharply from a time series high in 2013 to a value just above the time series mean (Fig. 13.3). Abundance values in 2014 declined from a time series high in 2013 to a value which although significantly lower is still approximately 2 times the time series mean.

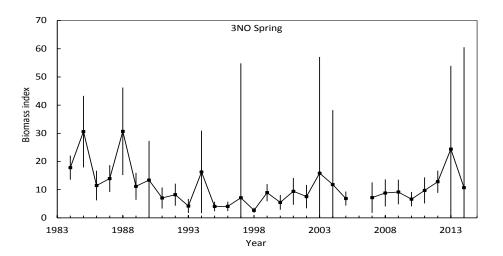

Fig. 13.3. Witch flounder in NAFO Divs. 3NO: biomass index from Canadian spring surveys. Vertical lines represent 95% confidence intervals. Values are Campelen units or, prior to 1996, Campelen equivalent units. Due to substantial coverage deficiencies values from 2006 are not presented.

Canadian autumn RV surveys. The biomass index in Divs. 3NO (Fig. 13.4) has shown a general increasing trend since 1996. The index increased substantially from 2007 to 2009 reaching the highest value in the series. From 2008 to 2013 the biomass index has been approximately twice the time series average. Due to operational difficulties there was no 2014 autumn survey in Divs. 3NO.

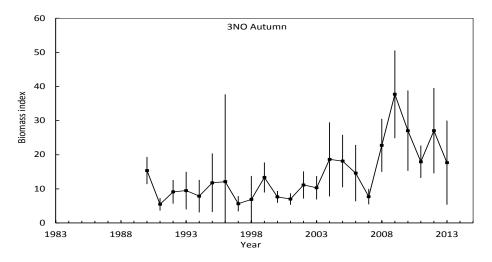

Fig. 13.4. Witch flounder in Divs. 3NO: biomass index from Canadian autumn surveys. Vertical lines represent 95% confidence limits. Values are Campelen units or, prior to 1995, Campelen equivalent units. Due to operational difficulties there was no autumn survey in 2014.

EU-Spain RV survey biomass. Surveys have been conducted annually from 1995 to 2014 by EU-Spain in the Regulatory Area in Divs. 3NO to a maximum depth of 1 462 m (since 1998). In 2001, the research vessel (R/V *Playa de Menduiña*) and survey gear (Pedreira) were replaced by the R/V *Vizconde de Eza* using a Campelen trawl (NAFO SCR Doc. 05/25). Data for witch flounder in Divs. 3NO prior to 2001 have not been converted and therefore data from the two time series cannot be compared. In the Pedreira gear series, the biomass increased from 1995-2000 but declined in 2001. In the Campelen gear series, the biomass index has been somewhat variable but generally decreased from 2001 to 2007. This was followed by an increase from 2007 to 2010 to levels near the previous series high of 2004. Since 2010, although variable, the biomass index has generally

decreased from 2010 to 2013. The biomass and abundance index from Spanish surveys in 2014 was the lowest of the 1995-2014 time series (Fig. 13.5).

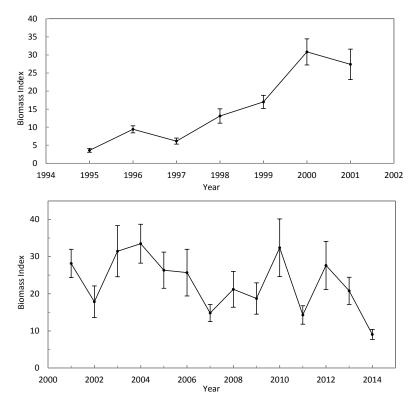

Fig. 13.5. Witch flounder in Divs. 3NO: biomass index from Spanish Divs. 3NO surveys (± 1 standard deviation). Data from 1995-2001 is in Pedreira units; data from 2001-2014 are Campelen units. Both values are present for 2001.

Abundance at length. Abundance at length in the Canadian surveys appears to be fairly consistent since 1995 with few fish greater than 50 cm, and a mode generally around 40 cm. However, from 2004 to 2014 there has been an increase in the number of fish in the 30-50 cm range. There have been very few strong peaks (presumably year classes) that could be followed in successive years. There have been no strong peaks at lengths less than 21 cm, which would possibly indicate large year classes, since 2002. The highest levels of small fish were in the late 1990s, and values since 2002 have been variable but mostly below the mean of the series.

Distribution. Analysis of distribution data from the surveys show that this stock is mainly distributed in Div. 30 along the southwestern slope of the Grand Bank. In most years the distribution is concentrated toward this slope but in certain years, an increased percentage may be distributed in shallower water. A 2014 analysis of biomass proportions by depth aggregated across survey years (spring 1984-2014 and fall 1990-2014) indicated that in Div. 3N both spring and autumn biomass proportions were fairly evenly distributed over a depth range of 57-914 m while those in Div. 30 were more restricted to shallower depth range of 57-183 m. Distributions of juvenile fish (less than 21 cm) appeared to be slightly more prevalent in shallower water during autumn surveys. It is possible however, that the juvenile distribution may be more related to the overall pattern of witch flounder being more widespread in shallower waters during the autumn. In years where all strata are surveyed to a depth of 1462 m in the autumn survey, generally less than 5% of the Divs. 3NO biomass was found in the deeper strata (731-1462 m).

c) **Estimation of Parameters**

A surplus production model in a Bayesian framework was used for the assessment of this stock. The input data were catch from 1960-2014, Canadian spring survey series from 1984-1990, Canadian spring survey series from 1991-2014 (no 2006) and the Canadian autumn survey series from 1990-2013.

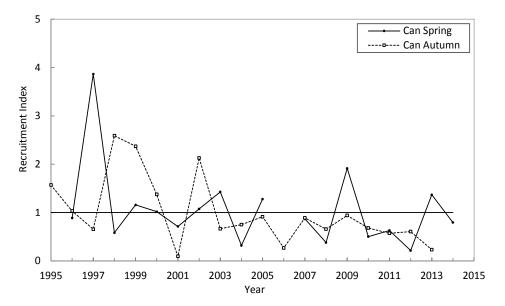

193

The priors used in the model were:

Parameter	Winbugs Specification	Prior Distribution
Initial population size	Pin~dunif(0.5, 1)	uniform(0.5 to 1)
Intrinsic rate of natural increase	r ~ dlnorm(-1.763,3.252)	lognormal (mean, precision)
Carrying capacity	K~dlnorm(4.562,11.6)	lognormal (mean, precision)
Survey catchability	pq ~dgamma(1,1)	gamma(shape, rate)
	q <-1/pq	
Process error	sigma ~ dunif(0,10)	uniform(0 to 10)
	isigma2 <- pow(sigma, -2)	
Observation error	tau~dgamma(1,1)	gamma(shape, rate)
	itau2 <- 1/tau	

d) Assessment Results

Recruitment: Recruitment (defined as fish less than 21cm) in both the spring and autumn Canadian surveys although somewhat variable has generally been low since 2002. Recruitment since 2005 has generally been lower than the time series average, although there were above average peaks indicated for spring recruitment in 2009 and 2013 (Fig. 13.6).

Stock Production Model: The surplus production model results indicate that stock size decreased from the late 1960s to the early 1990s and has increased since the late 1990s. The model suggests that a maximum sustainable yield (MSY) of 3 760 (80% CI: 2 965-4 820) t can be produced by total stock biomass of 59 680 (80% CI: 44 600-73 700) t (B_{msy}) at a fishing mortality rate (F_{msy}) of 0.06 (80% CI: 0.05-0.09).

Biomass: The analysis showed that relative population size (median B/B_{msy}) was below $B_{lim}=30\% B_{MSY}$ from 1993-1998. Biomass has since increased to a level of 81% B_{MSY} in 2014 (Fig. 13.7). The probability of being below B_{lim} in 2014 is very low.

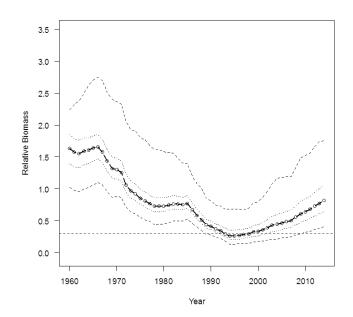

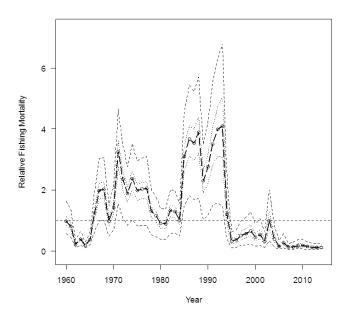

Fig. 13.7. Witch flounder in Divs. 3NO. Median relative biomass (*Biomass/B_{MSY}*) with 50% and 95% credible intervals. The horizontal line is $B_{lim}=30\% B_{MSY}$.

Fishing Mortality: Relative fishing mortality rate (median F/F_{msy}) was above 1.0 from the late 1960s to the mid-1990s (Fig. 13.8). *F* has been below F_{msy} since 1995. From 2010-2014 *F* averaged about 13% of F_{msy} . The probability of being above F_{lim} in 2014 is very low (<1%).

195

Fig. 13.8. Witch flounder in Divs. 3NO. Median relative fishing mortality (F/F_{MSY}) with 50% and 95% credible intervals. The horizontal line is $F_{lim}=F_{MSY}$.

e) State of the Stock

The stock size has steadily increased since 1999 and is now at 81% $B_{msy.}$ There is very low risk (<1%) of the stock being below B_{lim} or F being above F_{lim} . Recruitment (juveniles < 21 cm) since 2005 has generally been lower than the time series average. The stock is in the safe zone of the NAFO Precautionary Approach Framework (see section g).

f) Medium Term Considerations

The posterior distributions (13 500 samples) for *r*, *K*, sigma, and biomass and the production model equation were used to project the population to 2018. All projections assumed that the catch in 2015 was equal to the TAC of 1 000 t. This was followed by constant fishing mortality for 2016 and 2017 at several levels of *F* (F_{2015} , 75% F_{2015} , 125% F_{2015} , 2/3 F_{MSY} , 75% F_{MSY} , and 85% F_{MSY}). F_{2015} was taken as $F_{statusquo}$ as *F* in the reopened fishery is likely to be higher than that while the stock was under moratorium.

The probability that $F > F_{lim}$ in 2015 was less than 1% at a catch of 1 000 t (Table 13.1, 13.2). The probability of $F > F_{lim}$ increases to 26% at an F of 75% F_{MSY} . The population is projected to grow (Fig. 13.9) and the probability that the biomass in 2018 is greater than the biomass in 2014 is high under all scenarios. The population is projected to remain below B_{MSY} for all levels of F examined with a probability of greater than 50%.

Table 13.1.	Medium-term projections for witch flounder.	Estimates and 80% confidence interval for
	yield and relative biomass B_y/B_{msy} , are shown,	for projected F values of F_{2015} , 75% F2015,

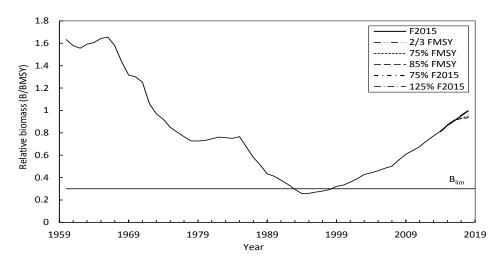

Fig. 13.9. Witch flounder in Divs. 3NO: medium term projections of relative biomass (B/B_{msy}) at four levels of *F* (*F*₂₀₁₅, 2/3 *F*_{msy}, 75% and 85% *F*_{msy}). A catch of 1 000 t is assumed in 2015.

g) Reference Points

In 2014 reference point proxies for B_{lim} and F_{lim} were derived from the Canadian spring survey series. This year reference points can be estimated from the surplus production model. Scientific Council considers that 30% B_{msy} is a suitable biomass limit reference point (B_{lim}) and F_{msy} a suitable fishing mortality limit reference point (here estimated to be 0.06) for stocks where a production model is used. The limit reference points derived from the surplus production model are not comparable to the proxies developed from the survey index.

At present, the risk of the stock being below B_{lim} or above F_{lim} are both very low at less than 1% and therefore the stock is in the safe zone as defined in the NAFO Precautionary Approach Framework (Fig. 13.10).

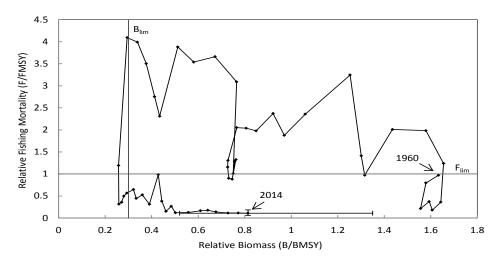

Fig.13.10. Witch flounder in Divs. 3NO: stock trajectory estimated in the surplus production analysis, under a precautionary approach framework.

The next full assessment of this stock will be in 2017.

14. Capelin (Mallotus villosus) in Divs. 3NO

(SCR Doc. 15/27)

a) Introduction

The fishery for capelin started in 1971 and catch was highest in the mid-1970s with a maximum catch of 132 000 t in 1975. The directed fishery was closed in 1992 and the closure has continued through 2014 (Fig. 14.1). No catches have been reported for this stock between 1993 and 2013.

Nominal catches (t) and TAC's (t) are as follows:

	2006	2007	2008	2009	2010	2011	2012	2013	2014	2015

na: no advice possible

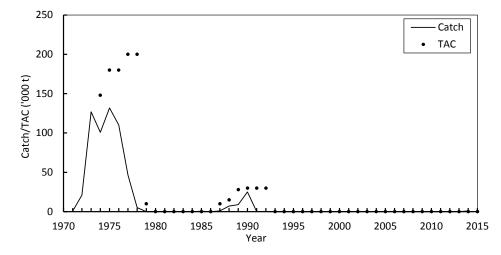

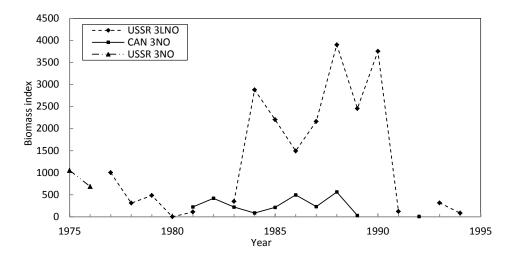

Fig. 14.1. Capelin in Divs. 3NO: catches and TACs.

Data Overview

b) Research survey data

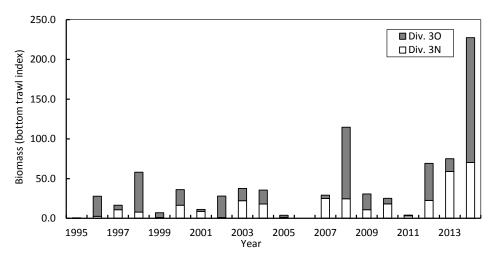

Acoustic surveys of the capelin stock in Divs. 3NO were conducted by the USSR/Russia in 1975-1994 and Canada in 1981-1992. Now, it is difficult to compare the results of these surveys since most of Russian suveys covered Divs. 3LNO. Maximum stock size was registered in 1988 and then an abrupt decline was observed after 1990 (Fig.14.2).

199

Fig. 14.2. Estimate of capelin stock according to the data of Russian and Canadian acoustic surveys in 1975-1994.

Trawl acoustic surveys of capelin on the Grand Bank previously conducted by Russia and Canada on a regular basis have not been repeated since 1995. In recent years, STACFIS has repeatedly recommended investigation of the capelin stock in Divs. 3NO utilizing trawl-acoustic surveys to allow comparison with historical time series. However, this recommendation has not been acted upon. The only indicator of stock dynamics presently available may be capelin biomass indices obtained during Canadian stratified-random spring trawl surveys. In 1996-2014, when a Campelen trawl was used as a sampling gear, survey biomass index of capelin in Divs. 3NO varied from 3.9 to 227 (Fig.14.3), and the average value for this period is 44. In 2005, survey biomass index of capelin in Divs. 3NO was 3.9, the lowest level since 1996; estimates in 2006 are not comparable because of poor coverage in that year. In 2008 the biomass index sharply increased to 114 and decreased in next three years to the level of 4.1 in 2011. In 2013 biomass index was 74.9 and it's considerably increased in 2014 to the highest level of the entire period – 227.

c) Estimation of Stock Parameters

Since interpolation by density of survey bottom trawl catches to the area of strata for such pelagic fish species as capelin can lead to significant deviation of the total biomass, the average value of all non-zero catches was used as an index for evaluation of the stock biomass in 1990-2014. The proportion of zero and non-zero catches remained relatively stable, however, if this proportion changes, the index may not be comparable between years.

Survey catches were standardized to 1 km² from Engel and Campelen trawl data. Sets, which did not contain capelin, were not included in account. The confidence intervals around the average catch index were obtained by bootstrapping of standardized catch values. According to data from 1996-2014, the mean catch varied between 0.06 and 1.56. In 2013 and 2014, this parameter was 0.51 and 0.98, respectively (Fig. 14.4).

Bottom-trawling is not a satisfactory basis for a stock assessment of a pelagic species and survey results are indicative only.

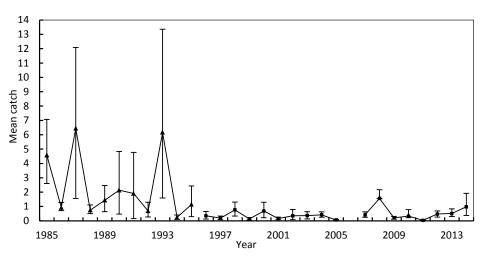

Fig. 14.4. Capelin in Divs. 3NO: mean catch from Canadian spring surveys in 1985-2014. Estimates prior to 1996 are from Engel and from 1996-2014 are from Campelen.

Assessment Results

Acoustic surveys series terminated in 1994 indicated a stock at a low level. Biomass indices from bottom trawl surveys since then have not indicated a change in stock status since then.

Precautionary Reference Points

STACFIS is not in a position to determine biological reference points for capelin in Divs. 3NO.

d) Research recommendations

STACFIS reiterates its **recommendation** that *initial investigations to evaluate the status of capelin in Divs. 3NO* should utilize trawl acoustic surveys to allow comparison with the historical time series.

This stock is expected next to be fully assessed in 2018.

15. Redfish (Sebastes mentella and Sebastes fasciatus) in Div. 30

Interim Monitoring Report (SCR Doc. 15/08; SCS Docs. 15/04, 05, 06, 07)

a) Introduction

There are two species of redfish that have been commercially fished in Div. 30; the deep-sea redfish (*Sebastes mentella*) and the Acadian redfish (*Sebastes fasciatus*). The external characteristics are very similar, making them difficult to distinguish, and as a consequence they are reported collectively as "redfish" in the commercial fishery statistics and RV surveys. Within Canada's fishery zone redfish in Div. 30 have been under TAC regulation since 1974 and with a minimum size limit of 22 cm since 1995, whereas catch was only regulated by mesh size in the NRA of Div. 30 prior to the Fisheries Commission adopting a TAC in 2004. Initially, TAC was implemented at a level of 20 000 t per year for 2005-2008 and it has remained at that level. This TAC applies to the entire area of Div. 30.

Nominal catches have ranged between 3 000 t and 35 000 t since 1960 and have been highly variable with several distinct periods of rapid increase and decrease (Fig. 15.1). Up to 1986 catches averaged 13 000 t,

increased rapidly and peaked at 35 000 t in 1988, then declined to 5 100 t by 1997. Catches increased to 20 000 t in 2001, declined to 4 000 t by 2008 and have since ranged between 5 200 t to 7 600 t with the 2014 catch estimated at 7 600 t.

	2006	2007	2008	2009	2010	2011	2012	2013	2014	2015
TAC	20	20	20	20	20	20	20	20	20	20
STATLANT 21	11	7.5	5.1	6.3	6.5	6.0	6.4	7.5	7.6	
STACFIS	12.6	5.2	4.0	6.4	5.2	6.0	6.4	7.5	7.6	

Nominal catches and TACs ('000 t) for redfish in the recent period are as follows:

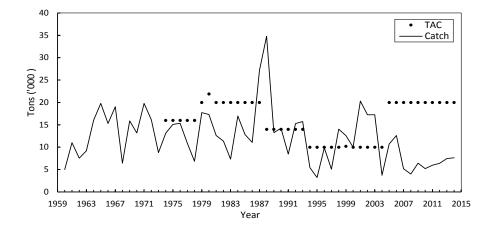

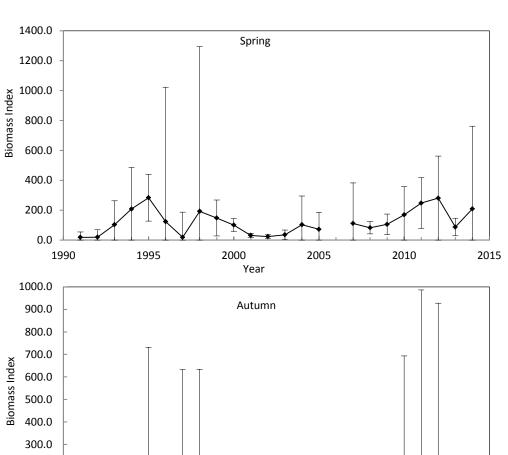

Fig. 15.1. Redfish in Div. 30: Catches and TACs.

b) Data Overview

Surveys. The Canadian spring survey was conducted in Div. 30 during 2014, but there was no autumn survey. The spring biomass index increased steadily from 2008 to 2012, while the autumn biomass index increased from 2008 to 2010, then it remained stable to 2012. In 2013, both indices fell to levels comparable to those observed in 2008-2009. For the spring and autumn series, the 2013 biomass index increased to approximately the 2010-2012 average. The recent trend in abundance from the surveys is very similar to the trend in biomass. A relatively strong year-class born in the early 2000s constitutes the best sign of recruitment since the relatively strong 1998 year-class.

c) Estimation of Stock Parameters

1995

200.0 100.0 0.0 1990

Fig. 15.2.

Catch/Biomass ratio. A fishing mortality proxy derived from the ratio of catch to survey biomass was relatively high from 2001 to 2003, but values since 2007 are among the lowest in the time series (Fig.15.3).

Year

(Campelen equivalent estimates prior to autumn 1995).

2005

Redfish in Div. 30: Survey biomass index from Canadian RV surveys in Div. 30

2010

2015

203

Fig. 15.3. Redfish in Div. 30: Catch/survey biomass ratios for Div. 30. Biomass was calculated as the average survey biomass between spring (n) and autumn (n-1) for year (n) in which catch was taken. The 2006 value of biomass comes from the autumn survey as there was no spring survey in 2006.

d) Conclusion

Catches were stable from 2009 to 2014. Survey indices increased or remained stable between years during the period 2009 to 2012, fell to below 2009 levels in 2013, but increased above 2009 levels in spring 2014. There was no survey in autumn 2014. Persistent and high variability in the indices makes it difficult to reconcile year to year changes. Current fishing mortality proxy is low. Therefore, there is nothing to indicate a change in the status of the stock. The next full assessment of this stock is planned to be in 2016.

e) Research Recommendations

STACFIS recommended that for Redfish in Div. 30, a recruitment index be developed for this stock.

STATUS: No progress on this recommendation; it will be addressed during the next full assessment.

16. Thorny skate (Amblyraja radiata) in Divs. 3LNO and Subdiv. 3Ps

Interim Monitoring Report (SCR Docs. 15/09, 20; SCS Docs. 15/05, 06, 07)

a) Introduction

Thorny skate on the Grand Banks was first assessed by Canada for the stock unit Divs. 3LNOPs. Subsequent Canadian assessments also provided advice for Divs. 3LNOPs. However, Subdiv. 3Ps is presently managed as a separate unit by Canada and France in their respective EEZs, and Divs. 3LNO is managed by NAFO.

i) Catch History

Commercial catches of skates comprise a mix of skate species. However, thorny skate dominates, constituting about 95% of the skate species taken in the commercial fishery. Thus, the skate fishery on the Grand Banks can be considered a fishery for thorny skate. In Subdiv. 3Ps, Canada has established a TAC of 1 050 t. In 2005, NAFO Fisheries Commission established a TAC of 13 500 t for thorny skate in Divs. 3LNO. For 2010 and 2011, the TAC for Divs. 3LNO was reduced to 12 000 t. The TAC was further reduced to 8 500 t for 2012, and to 7 000 t for 2013-2015.

Landings from Divs. 3LNO increased in the mid-1980s with the commencement of a directed fishery for thorny skate. The main participants in this new fishery were EU-Spain, EU-Portugal, Russia, and Canada. Landings reported by all countries in Divs. 3LNOPs over 1985-1991 averaged 18 066 t, with a peak of 29 048 t in 1991 (STATLANT 21A). From 1992-1995, landings of thorny skate declined to an average of 7 554 t; however, there are substantial uncertainties concerning reported skate landings prior to 1996. Average annual STACFIS landings in Divs. 3LNO for 2009-2012 was 5 235 t. STACFIS-agreed landings for

Divs. 3LNO was 4 353 t in 2013, and 4 487 t in 2014. Average annual landings (STATLANT 21A) for Subdiv. 3Ps in 2009-2012 was 468 t. Reported landings for Subdiv. 3Ps were 286 t in 2013, and 201 t in 2014.

Recent reported landings and TACs ('000 t) in Divs. 3LNO and Subdiv. 3Ps are as follows:

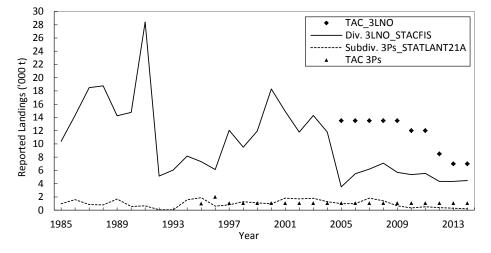

Fig. 16.1. Thorny skate in Divs. 3LNO and Subdiv. 3Ps, 1985-2014: reported landings and TAC.

b) Data Overview

i) Commercial fisheries

Thorny skates from either commercial or research survey catches are currently not aged.

Commercial length frequencies of skates were available for EU-Spain (1985-1991, 1997-2009, 2012, 2014), EU-Portugal (2002-2004, 2006-2011, 2013), Russia (1998-2008, 2011-2012, 2014), and Canada (1994-2008, 2010, 2012).

No standardized commercial catch per unit effort (CPUE) exists for thorny skate.

ii) Research surveys

Canadian spring surveys. Stratified-random research surveys have been conducted by Canada in Div. 3LNO and Subdiv. 3Ps in spring, using a Yankee 41.5 otter trawl in 1972-1982, an Engel 145 otter trawl in 1983-1995, and a Campelen 1800 shrimp trawl in 1996-2014. Subdiv. 3Ps was not surveyed in 2006, nor was the

deeper portion (>103 m) of Divs. 3NO in that year, due to mechanical difficulties on Canadian research vessels.

Indices for Divs. 3LNOPs in 1972-1982 (Yankee series) fluctuated without trend (Fig. 16.2a).

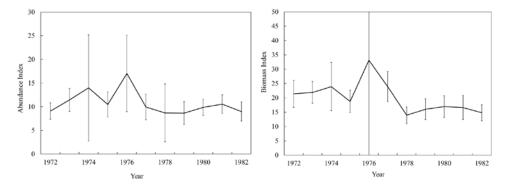

Fig. 16.2a. Thorny Skate in Divs. 3LNOPs, 1972-1983: abundance (left panel) and biomass (right panel) indices from Canadian spring surveys.

Standardized mean number and mean weights per tow for Div. 3LNOPs are presented in Fig. 16.2b. Catch rates of thorny skate in Divs. 3LNOPs declined from the mid1980s until the early 1990s. Since 1997, biomass indices have been increasing very slowly from low levels, while abundance indices remain relatively stable at very low levels.

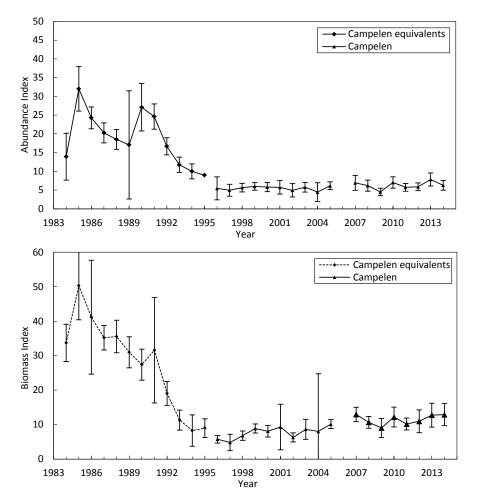

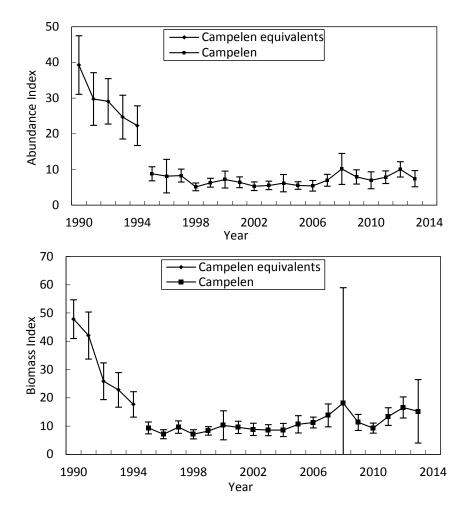

Fig. 16.2b. Thorny skate in DivS. 3LNOP, 1984-2014: abundance (top panel) and biomass (bottom panel) indices from Canadian spring surveys. The survey in 2006 was incomplete, due to mechanical difficulties on Canadian research vessels.

Canadian autumn surveys. Stratified-random surveys have been conducted by Canada in Divs. 3LNO in the autumn, using an Engel 145 otter trawl in 1990-1994 and a Campelen 1800 shrimp trawl in 1995-2014, to depths of \sim 1 450 m.

Autumn survey indices, similar to spring estimates, declined during the early 1990s. Catch rates have been stable at very low levels since 1995 (Fig. 16.3). Divs. 3NO were not sampled in 2014 due to mechanical difficulties on Canadian research vessels; thus, the biomass index represents only Div. 3L in that year. Autumn indices of abundance and biomass are, on average, higher than spring estimates. This is expected, because thorny skates are found deeper than the maximum depths surveyed in spring (~750 m), and are more deeply distributed during winter/spring.

207

Fig. 16.3. Thorny skate in Divs. 3LNO, 1990-2014: abundance (top panel) and biomass (bottom panel) indices from Canadian autumn surveys. Divs. 3NO were not sampled in 2014, due to mechanical difficulties on Canadian research vessels.

EU-Spain Divs. 3NO survey. The biomass trajectory from the EU-Spain surveys was very similar to that of Canadian spring surveys until 2006 (Fig. 16.4). In 2007, the two indices diverged: the EU-Spain index declined, while the Canadian Divs. 3NO biomass index fluctuated within a narrow range. A comparison of survey biomass within common sampled strata between both time series found little difference between 1997-2005 and 2007-2010. Differences in biomass indices appear to result from poor catch rates in the EU-Spain survey of deeper strata that were not sampled by Canadian surveys. In 2012, both biomass indices increased from 2011 levels. In 2013, the two indices diverged: the EU-Spain index declined, while the Canadian index increased. In 2014, biomass indices declined in surveys by both countries.

<u>Å</u>

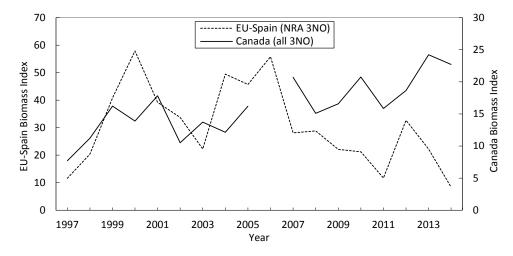

Fig. 16.4. Thorny skate in Divs. 3NO: biomass indices from the EU-Spain spring survey and Canadian spring survey in 1997-2014.

EU-Spain Div. 3L survey. EU-Spain survey indices in the NRA of Div. 3L are available for 2003-2014 (excluding 2005). The stratified random spring survey is conducted by the R/V *Vizconde de Eza* using a Campelen bottom trawl. The survey only occurs in the NAFO Regulatory Area (Flemish Pass), thus not sampling the entire Division. Both the EU-Spain and Canadian autumn Div. 3L biomass indices generally declined from 2007-2011, while the Canadian spring index was more variable during this period (Fig. 16.5). Recent Canadian biomass estimates have been relatively stable since 2010, while the EU-Spain index has been increasing relative to 2011.

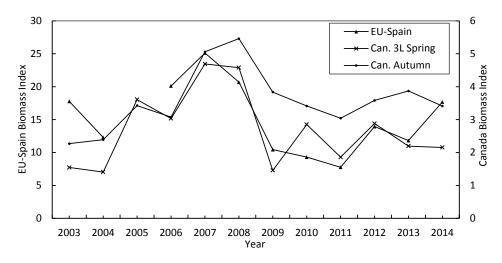

Fig. 16.5. Thorny skate in Div. 3L: Biomass indices from EU-Spain Div. 3L survey and the Canadian spring and autumn surveys of Div. 3L in 2003-2014.

c) Conclusion

With an update of abundance and biomass indices to 2014, there is nothing to indicate a significant change in the status of this stock.

The next assessment of this stock is planned for 2016.

17. White Hake (Urophycis tenuis) in Divs. 3NO and Subdiv. 3Ps

(SCR Docs. 15/09, 22, 23, 40; SCS Docs. 15/05, 06, 07, 08, 09; FC Doc. 15/01)

a) Introduction

The advice requested by Fisheries Commission is for NAFO Divs. 3NO. Previous studies indicated that white hake constitute a single unit in Divs. 3NOPs, and that fish younger than 1 year, 2+ juveniles, and mature adults distribute at different locations in Divs. 3NO and Subdiv. 3Ps. This movement of fish of different life stages between areas must be considered when assessing the status of white hake in Divs. 3NO. Therefore, an assessment of Divs. 3NO white hake is conducted with information on Subdiv. 3Ps included.

Canada commenced a directed fishery for white hake in 1988 in Divs. 3NO and Subdiv. 3Ps. All Canadian landings prior to 1988 were as bycatch in various groundfish fisheries. EU-Spain and EU-Portugal commenced a directed fishery in 2002, and Russia in 2003, in the NAFO Regulatory Area (NRA) of Div. 3NO; resulting in the 2003-2004 peak. There were no directed fisheries by EU-Spain in 2004 or by EU-Spain, EU-Portugal, or Russia in 2005-2014. In 2003-2004, 14% of the total landings of White Hake in Div. 3NO and Subdiv. 3Ps were taken by Canada, but increased to 93% by 2006; primarily due to the absence of a directed fishery for this species by other countries. A TAC for white hake was first implemented by Fisheries Commission in 2005 at 8 500 t, and then reduced to 6 000 t for 2010-2011. The TAC in Div. 3NO for 2012 was 5 000 t, and 1 000 t for 2013-2015¹.

From 1970-2009, white hake landings in Div. 3NO fluctuated, averaging approximately 2 000 t, exceeding 5 000 t in only three years during that period. Landings peaked in 1987 at approximately 8 100 t (Fig. 17.1). With the restriction of fishing by other countries to areas outside Canada's 200-mile limit in 1992, non-Canadian landings fell to zero. Landings were low in 1995-2001 (422-t average), then increased to 6 718 t in 2002 and 4 823 t in 2003; following recruitment of the large 1999 year-class. STACFIS-agreed catches decreased to an average of 386 t in 2008-2012. Catches declined to 203 t and 273 t in 2013 and 2014 respectively in Divs. 3NO.

Commercial catches of white hake in Subdiv. 3Ps were less variable, averaging 1 114 t in 1985-93, then decreasing to an average of 619 t in 1994-2002 (Fig. 17.1). Subsequently, catches increased to an average of 1 174 t in 2004-2007, then decreased to a 368-t average in 2008-2012. Catches declined to 167 t in 2013, and increased to 354 t in 2014.

Recent reported landings and TACs (000 tons) in NAFO Divs. 3NO and Subdiv. 3Ps are as follows:

 $^1\mbox{May}$ change in-season. See NAFO FC Doc. 15/01 quota table.

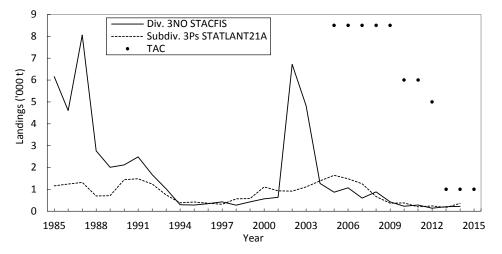

Fig. 17.1. White hake in Divs. 3NO and Subdiv. 3Ps: Total catch of white hake in NAFO Divs. 3NO (STACFIS), and Subdiv. 3Ps (STATLANT-21A). The Total Allowable Catch (TAC) in the NRA of Divs. 3NO is also indicated on the graph.

b) Input Data

i) Commercial fishery data

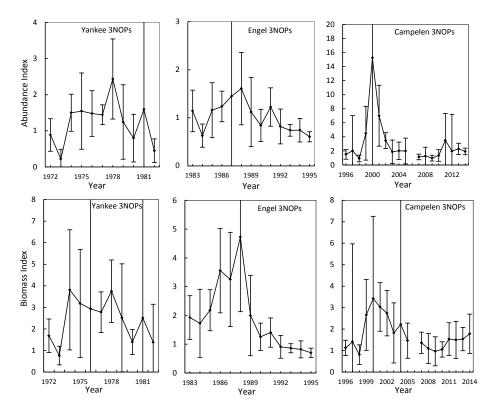

Length composition. Length frequencies were available for Canada (1994-2012), EU-Spain (2002, 2004, 2012, 2014), EU-Portugal (2003-2004, 2006-2014), and Russia (2000-2007, 2013). In the Canadian fishery in 2004-2012, peak lengths caught by longlines in Div. 30 and Subdiv. 3Ps were generally 58-78 cm, although in Subdiv. 3Ps in 2012 the fishery caught a contracted range of mainly 50-63 cm white hake. For that period, gillnets in Div. 30 and Subdiv. 3Ps caught mainly 64-78 cm fish. Sizes reported from commercial trawls fishing in the NRA of Divs. 3NO by EU-Spain in 2012 were 27-52 cm, and 21-80 cm in 2014. EU-Portugal reported 24-76 cm fish in 2013, and 24-67 cm fish in 2014. Russia reported 39-75 cm white hake in 2013, and 35-45 cm fish from a small sample in 2014.

ii) Research survey data

Canadian stratified-random bottom trawl surveys. Data from spring research surveys in NAFO Div. 3N, 3O, and Subdiv. 3Ps were available from 1972 to 2014. In the 2006 Canadian spring survey, most of Subdiv. 3Ps was not surveyed, and only shallow strata in Divs. 3NO (to a depth of 77 m in Div. 3N; to 103 m in Div. 3O) were surveyed; thus the survey estimate for 2006 was not included. Data from autumn surveys in Divs. 3NO were available from 1990 to 2013, due to mechanical difficulties the survey was not completed in 2014. Canadian spring surveys were conducted using a Yankee 41.5 bottom trawl prior to 1984, an Engel 145 bottom trawl from 1984 to 1995, and a Campelen 1800 trawl thereafter. Canadian autumn surveys in Divs. 3NO were conducted with an Engel 145 trawl from 1990 to 1994, and a Campelen 1800 trawl from 1995-2014. There are no survey catch rate conversion factors between trawls for white hake; thus each gear type is presented as a separate time series.

Abundance and biomass indices of white hake from the Canadian spring research surveys in Divs. 3NOPs are presented in Fig. 17.2a. From 2003-2014, the population remained at a level similar to that previously observed in the Campelen time series for 1996-1998. The dominant feature of the white hake abundance time series was the large peak observed over 2000-2001. In recent years, spring abundance of white hake increased in 2011, but declined to stable levels over 2012-2014. Biomass of this stock increased in 2000, generated by the very large 1999 year-class. Subsequently, the biomass index decreased until 2009, and has since increased in 2014 to the average level observed from 1996-2014.

. A.A

211

Fig. 17.2a. White hake in Divs. 3NO and Subdiv. 3Ps: abundance (top panels) and biomass (bottom panels) indices from Canadian spring research surveys, 1972-2014. Estimates from 2006 are not shown, since survey coverage in that year was incomplete. Yankee, Engel, and Campelen time series are not standardized, and thus are presented on separate panels. Error bars are 95% confidence limits. The bounds of the error bars in 1976, 1981, 1987 and 2000 in some panels extend above/below the graph limits.

Canadian autumn surveys of Divs. 3NO have the peak in abundance represented by the very large 1999 yearclass (Fig. 17.2b). Autumn indices then declined to levels similar to those observed during 1996-1998 until 2010. In recent years, both biomass and abundance appear to have slightly increased. This survey was not completed in 2014

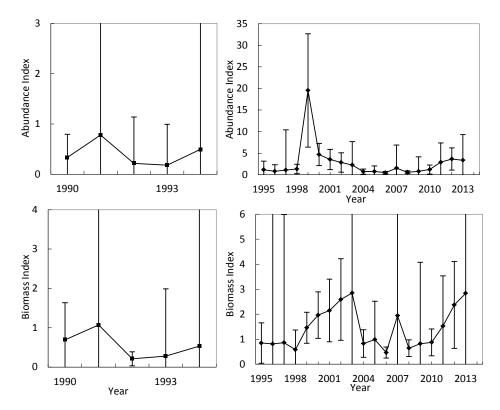

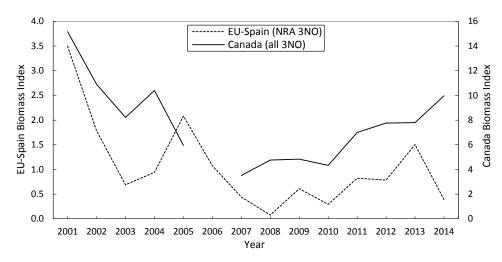

Fig. 17.2b White hake in Divs. 3NO: abundance (top panel) and biomass indices (bottom panel) from Canadian autumn surveys, 1990-2013. Engel (1990-1994) and Campelen (1995-2013) time series are not standardized. Estimates from 2014 are not shown, since survey coverage in that year was incomplete. Error bars are 95% confidence limits. The bounds of the error bars in 1991, 1994, 2002, 2003 2009 and 2013 in some panels extend above/below the graph limits.

EU-Spanish stratified-random bottom trawl surveys in the NRA. EU-Spain biomass indices in the NAFO Regulatory Area (NRA) of Divs. 3NO were available for white hake from 2001 to 2014 (Fig. 17.3). EU-Spain surveys were conducted with Campelen gear (similar to that used in Canadian surveys) in the spring to a depth of 1 400 m. The EU-Spain biomass index was highest in 2001, then declined to 2003, peaked slightly in 2005, and then declined to its lowest level in 2008. In 2009-2013, the EU-Spain index indicated a gradually increasing trend relative to 2008, which is similar to that of the Canadian spring survey index (Fig. 17.3). However, the EU-Spain biomass index declined in 2014, while the Canadian index increased.

213

Fig. 17.3. White hake in the NRA of Divs. 3NO: Biomass indices from EU-Spain Campelen spring surveys in 2001-2014 compared to Canadian spring survey indices in all of Divs. 3NO. Estimates from 2006 Canadian survey are not shown, since survey coverage in that year was incomplete.

iii) Biological studies

Distribution. White hake in Divs. 3NO and Subdiv. 3Ps are confined largely to an area associated with the warmest bottom temperatures (4-8°C) along the southwest edge of the Grand Banks, edge of the Laurentian Channel, and southwest coast of Newfoundland.

White hake distribute in different locations during various stages of their life cycle. Fish <27 cm in length (1st year fish) occur almost exclusively on the Grand Bank in shallow water. Juveniles (2+ years) are widely spread, and a high proportion of white hake in the Laurentian Channel area of Subdiv. 3Ps are juveniles. Mature adults concentrate on the southern slope of the Bank in Div. 3NO, and along the Laurentian Channel in Subdiv. 3Ps.

Maturity. Maturity at size was estimated for each sex separately, using Canadian Campelen spring survey data from 1996-2014 (Fig. 17.4). Length at 50% maturity (L_{50}) is different between sexes; with fifty percent of males maturing at 39 cm, and fifty percent of females maturing at 54 cm. However, L_{50} was very similar for each sex between Divs. 3NO and Subdiv. 3Ps.

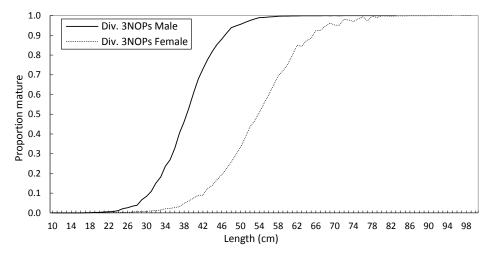

Fig. 17.4. White hake in Divs. 3NO and Subdiv. 3Ps: ogives calculated for each sex from Canadian spring surveys, and averaged over 1996-2014 (excluding 2006).

Life stages. Canadian spring survey trends in abundance for 1996-2014 were staged based on length as oneyear-olds, 2+ juveniles, and mature adults (Fig. 17.5). Recruitment of one-year-old male and female white hake was highest in 2000, and has since declined. There are currently no indications of increased abundance of mature white hake. For males, the abundance of immature white hake increased slightly in 2012 and 2014, while a similar peak appeared in 2012 for females.

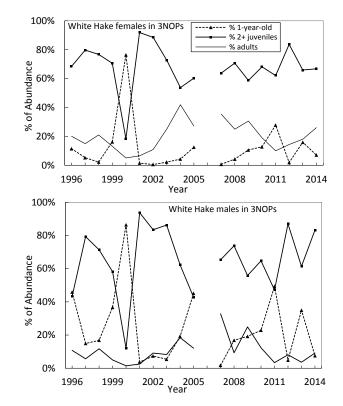

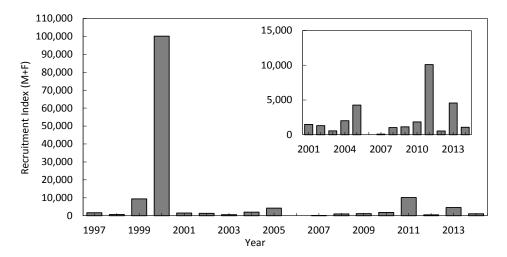

Fig. 17.5. White hake in Divs. 3NO and Subdiv. 3Ps: proportion of stages in terms of abundance by sex from Canadian Campelen spring survey data in 1996-2014. Estimates from 2006 are not shown, since survey coverage in that year was incomplete.

iv) Recruitment

In Canadian spring research surveys, the number of white hake less than 27 cm in length is assumed to be an index of recruitment at Age 1. The recruitment index in 2000 was very large, but no large value has been observed during 2001-2014 (Fig. 17.6). The index of recruitment for 2011 was comparable to that seen in 1999, and a smaller peak in 2013 was similar to one in 2005.

215

Fig. 17.6. White hake in Divs. 3NO and Subdiv. 3Ps: recruitment index for Age 1 males and females (combined) from Canadian Campelen spring surveys in Divs. 3NO and Subdiv. 3Ps in 1997-2014. Estimates from 2006 are not shown, since survey coverage in that year was incomplete. Inset plot depicts 2001-2014 on a smaller scale.

c) Assessment Results

Biomass. Biomass of this stock increased in 1999 and 2000, generated by the large recruitment observed in those years. Subsequently, the biomass index decreased, and has since increased in 2014 to the average level observed from 1996-2014.

Recruitment. Recruitment in 2000 was very large, but no large year class has been observed since then. Recruitment was higher in 2011, but not comparable to the very high recruitment observed in 2000.

Relative *F* (commercial landings/Canadian spring survey biomass). Using STACFIS-agreed commercial landings and Canadian spring survey biomass index, estimates of relative *F* were calculated for white hake in Divs. 3NO and Divs. 3NOPs. Relative fishing mortality (Rel. *F*) has fluctuated, but increased considerably in 2002-2003 (Fig. 17.7). Current estimates of Relative *F* are low.

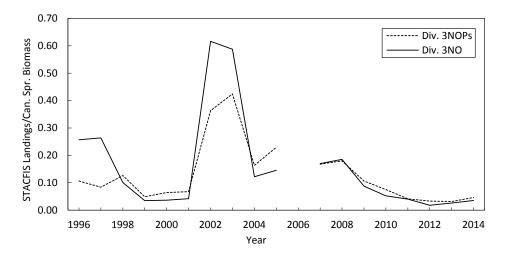

Fig. 17.7. White hake in Divs. 3NO and Subdiv. 3Ps: estimates of relative *F* from STACFIS-agreed commercial landings/Canadian Campelen spring survey biomass (1996-2014). Estimates from 2006 are not shown, since survey coverage in that year was incomplete.

. A. A

State of the stock. The stock biomass is at an average level. No large recruitments have been observed since 2000. Recruitment was higher in 2011, but not comparable to the very high recruitment observed in 2000. Fishing mortality is low.

d) Other Studies

Limit reference points for white hake were investigated using Bayesian surplus production models, catchresilience models and empirical reference points from the Campelen survey series (SCR Doc. 15/40). Due to diagnostics of the Bayesian model, in particular large process error, the model was not accepted as a basis for assessment nor for setting limit reference points. Catch-resilience models were also not accepted due to the dependency of the model exclusively on catch, which historically is questioned and on initial conditions in the model. The empirical reference points investigated were not accepted due to uncertainty in how to apply them to a population with episodic recruitment.

e) Reference Points

No precautionary reference points have been established for this stock.

f) Research Recommendations

STACFIS **recommended** that age determination should be conducted on otolith samples collected during annual Canadian surveys (1972-2014+); thereby allowing age-based analyses of this population.

STATUS: Otoliths are being collected, but have not been aged. STACFIS reiterates this recommendation.

STACFIS **recommended** that the collection of information on commercial catches of white hake be continued and now include sampling for age, sex and maturity to determine if this is a recruitment fishery.

STATUS: No progress, STACFIS reiterates this recommendation.

STACFIS **recommended** that survey conversion factors between the Engel and Campelen gear be investigated for this stock.

STATUS: No progress, STACFIS reiterates this recommendation.

STACFIS **recommends** that work continue on the development of population models and reference point proxies.

The next full assessment of this stock is planned for 2017.

D. WIDELY DISTRIBUTED STOCKS: SA 2, SA 3 AND SA 4

(SCR Docs. 15/05, 10, 11, 15; SCS Doc. 15-08)

Recent Conditions in Ocean Climate and Lower Trophic Levels

• Ocean climate composite index for SA2-4 remain above normal in 2014 and recent years but the overall trend has been in decline approaching the long-term average.

217

• The composite spring bloom index has remained below normal in 2013-2014 after a positive phase extending back to 2006.

• The composite zooplankton increased substantially in 2014 reaching a record-high value.

• The composite trophic index reached a record-high in 2014 being strongly influenced by standing stocks of zooplankton.

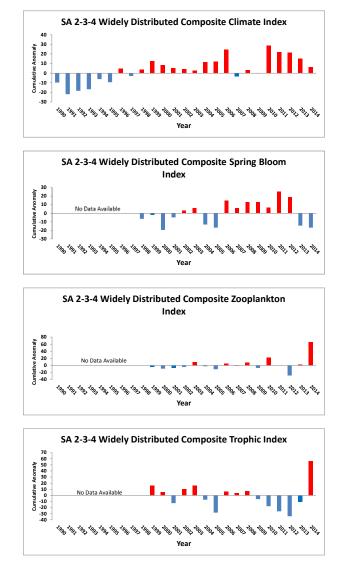

Fig. 18. Composite ocean climate index for Subarea 2-3-4 (widely distributed stocks) derived by summing the standardized anomalies (top panel) during 1990-2014, composite spring bloom (summed anomalies for the magnitude (integral during bloom) and peak intensity-amplitude metrics) index during 1998-2014, and composite trophic (summed nutrient and standing stocks of phyto- and zooplankton indices) index (bottom panel) during 1999-2014.

- A.A

Environmental Overview

Sub-polar waters cover much of Newfoundland and Labrador Shelf with sub-surface temperatures of -1-2°C and salinities in the range of 32-33.5. Labrador Slope Water flows southward along the shelf edge and into the Flemish Pass region, this water mass is generally warmer and saltier than the sub-polar shelf waters with a temperature range of 3°-4°C and salinities in the range of 34-34.75. On average bottom temperatures remain <0°Cover most of the northern Grand Banks but increase to 1-4°C in southern regions and along the slopes of the banks below 200 m. North of the Grand Bank, in Div. 3K, bottom temperatures are generally warmer (1- 3° C) except for the shallow inshore regions where they are mainly $<0^{\circ}$ C In general, shelf water masses undergo seasonal modification in their properties due to the seasonal cycles of air-sea heat flux, wind-forced mixing and ice formation and melt, leading to intense vertical and horizontal gradients particularly along the frontal boundaries separating the shelf and slope water masses. Temperature and salinity conditions in the Scotian Shelf, Bay of Fundy and Gulf of Maine regions are determined by many processes: heat transfer between the ocean and atmosphere, inflow from the Gulf of St. Lawrence supplemented by flow from the Newfoundland Shelf, exchange with offshore slope waters, local mixing, freshwater runoff, direct precipitation and melting of sea-ice. The Nova Scotia Current is the dominant inflow, originating in the Gulf of St. Lawrence and entering the region through Cabot Strait. The Current, whose path is strongly affected by topography, has a general southwestward drift over the Scotian Shelf and continues into the Gulf of Maine where it contributes to the counter-clockwise mean circulation. The properties of shelf waters are modified by mixing with offshore waters from the continental slope. These offshore waters are generally of two types, Warm Slope Water, with temperatures in the range of 8-13°C and salinities from 34.7-35.6, and Labrador Slope Water, with temperatures from 3.5°C to 8°C and salinities from 34.3 to 35. Shelf water properties have large seasonal cycles, east-west and inshore-offshore gradients, and vary with depth.

Ocean Climate and Ecosystem Indicators

The ocean climate composite index representing conditions from Labrador to the Scotian Shelf (SA2-4) remained above normal in 2014 and recent years but the overall trend has been in decline since 2010 approaching the long-term average (Fig. 18). Sea surface temperature (SST) from the Labrador Shelf all the way south to the Scotian Shelf were above normal in 2014, however, it was a year of extremes in many areas with near record low values in winter to record highs during the summer. Winter time convection in the Labrador Sea during 2014 reached to 1 800 m, significantly deeper than most years. While water column and bottom temperatures were below normal in many areas of the NL Shelf they remained significantly above normal on the Scotian Shelf at the second highest level in 45 years. The composite spring bloom index has declined in 2013-2014 compared to positive anomalies observed back to 2006 (Fig. 18). The composite zooplankton index has returned to a record-high in 2014 due to remarkable positive anomalies observed in invertebrate taxa (Fig. 18). The composite trophic index also reached a peak in 2014 due to the substantial increase observed in the lower trophic levels (Fig. 18).

The increasing decadal trend of the total inorganic carbon and decreasing trend of pH within the Labrador Sea continue into 2014. The biomass indices of the spring bloom were below normal across most of the northwest Atlantic in 2014 with 18/19 of 24 sub-regions showing negative anomalies respectively. The timing indices of the spring bloom were later on average and limited in 2014. Although the standing stocks of zooplankton reached a record-high in 2014 with higher abundance of small grazing copepods along with non-copepod taxa, the Subarctic and Arctic calanoid copepods, which are important in energy transfer to higher trophic levels, remain in decline in recent years (2013-2014) over the northwest Atlantic.

18. Roughhead Grenadier (Macrourus berglax) in SAs 2 and 3

Interim Monitoring Report (SCS Docs. 15/04, 05, 06, 07; SCR Docs. 98/57, 15/09, 17, 20)

a) Introduction

STATLANT 21A

STACFIS

The stock structure of this species in the North Atlantic remains unclear because there is little information on the number of different populations that may exist and the relationships between them. Roughhead grenadier is distributed throughout NAFO Subareas 0 to 3 in depths between 300 and 2 000 m. However, for assessment purposes, NAFO Scientific Council considers the population of Subareas 2 and 3 as a single stock.

A substantial part of the grenadier catches in Subarea 3 previously reported as roundnose grenadier has been roughhead grenadier. To correct the catch statistics STACFIS (NAFO SCR Doc. 98/57) revised and approved roughhead grenadier catch statistics since 1987. In recent years (2010-2012), catches for the Subareas 2+3 roughhead grenadier were quite stable at levels around 1 000 t. In 2013 catches were 398 t and in 2014 were 613 t. (Fig. 18.1). Most of the catches were taken in Divs. 3LMN by EU-Spain, EU-Estonia and EU-Portugal fleets. In the catch series available, less than 2% of the yearly catch has been taken in Subarea 2.

Year

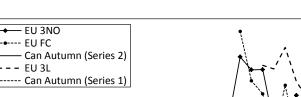

b) Data Overview

i) Surveys

There are no surveys indices available covering the total distribution, in depth and area, of this stock. According to other information this species is predominant at depths ranging from 800 to 1 500 m, therefore the best survey indicators of stock biomass should be the series extending to 1 500 m depth as they cover the depth distribution of roughhead grenadier fairly well. Figure 18.2 presents the biomass indices for the following series: Canadian autumn Divs. 2J+3K Engel (1978-1994, Series 1) and Canadian autumn Divs. 2J+3K Campelen (1995-2014, Series 2), EU Divs. 3NO (1997-2014), EU Div. 3L (2006-2014) and EU Flemish Cap (to1 400 m; 2004-2014). An increase is shown from 1995 until 2004-2008 for all available indices. Since then all the indices show a clear decreasing trend, except the Canadian autumn Divs. 2J+3K index that shows an increasing trend throughout the entire 1995-2014 period. The EU Div. 3L survey has been higher than the 2012 level in the past two years.

15

12

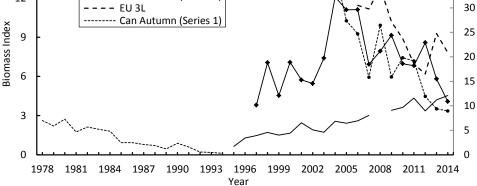

Fig. 18.2. Roughhead grenadier in Subareas 2+3: Survey biomass indices for roughhead grenadier.

The catch-biomass (C/B) ratios have a clear declining trend in the period 1995-2005 and since then are stable at low levels (Fig. 18.3). The (C/B) ratio remains low since 2008 despite the decline of many of the surveys biomass indices because catches levels in the last years are very low.

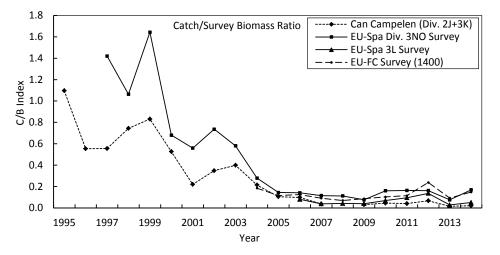

Fig. 18.3. Roughhead grenadier in Subareas 2+3: catch/biomass survey indices based upon Canadian autumn (Campelen series), Spanish Divs. 3NO, Spanish Div. 3L and EU-Flemish Cap (to 1 400 m depth).

c) Conclusion

Based on overall indices for the current year, there is no significant change in the status of the stock: survey indices indicate a stable (EU Div. 3L and Canadian autumn Divs. 2J+3K indices) or declining stock (EU Flemish Cap and EU Divs. 3NO surveys) in recent years. Fishing mortality indices have remained at low levels since 2005.

The next full assessment of this stock is planned to be in 2016.

40

35

19. Witch Flounder (Glyptocephalus cynoglossus) in Divs. 2J+3KL

Interim Monitoring Report (SCR Doc. 13/39; SCS Docs. 15/05, 07)

a) Introduction

A moratorium on directed fishing on this stock was implemented in 1995 following drastic declines in catch from the mid-1970s, and catches since then have been low levels of by-catch in other fisheries. From 1999 to 2004 catches were estimated to be very low, between 300 and 800 t and from 2005-2014, catches averaged less than 150 t.

	2006	2007	2008	2009	2010	2011	2012	2013	2014	2015

STACFIS	0.1	0.1	0.1	0.1	0.2	0.2	0.2	0.2	0.2	

Recent catches and TACs ('000 tons) are as follows:

ndf no directed fishing

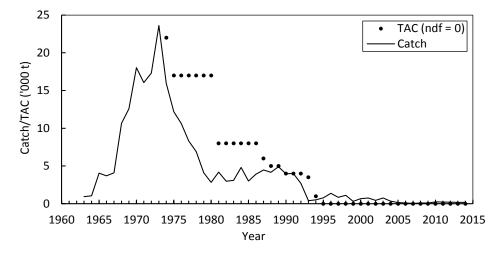

Fig. 19.1. Witch flounder in Divs. 2J, 3K and 3L: catches and TAC.

b) Data Overview

i) Surveys

Canadian autumn surveys were conducted in Divs. 2J, 3K and 3L beginning in 1977, 1978 and 1984 respectively and continued to 2014 (Fig 19.2). The survey biomass estimates showed a rapid decline from the mid-1980s to 1995, remained at very low levels and then showed a general increasing trend from 2003 to 2014.

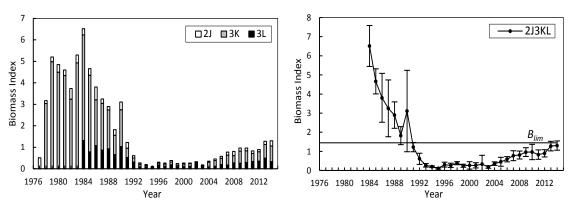

Fig. 19.2. Witch flounder in Divs. 2J, 3K and 3L: Index of biomass from Canadian autumn surveys by Division (left panel) and overall with 95% confidence limits (right panel). Values are Campelen units or, prior to 1995, Campelen equivalent units.

c) Conclusion

There was an increase in the survey biomass index from 2003 to 2014, nevertheless, the stock remains below B_{lim} , with a probability of 0.88 of being below B_{lim} in 2014. Based on survey indices for the current year, there is nothing to indicate a change in the status of the stock.

The next full assessment of this stock is scheduled for 2016.

20. Greenland Halibut (Reinhardtius hippoglossoides) in SA 2 + Divs. 3KLMNO

(SCR Docs. 15/07, 17, 19, 22, 41 12/19; SCS Docs. 15/04, 05, 06, 07, 08; FC Docs. 03/13, 10/12, 13/23)

a) Introduction

Fishery and Catches. TACs prior to 1995 were set autonomously by Canada; subsequent TACs have been established by NAFO Fisheries Commission (FC). Catches increased sharply in 1990 due to a developing fishery in the NAFO Regulatory Area in Divs. 3LMNO and continued at high levels during 1991-94. The catch was only 15 000 to 20 000 t per year in 1995 to 1998. The catch increased since 1998 and by 2001 was estimated to be 38 000 t, the highest since 1994. The estimated catch for 2002 was 34 000 t. The 2003 catch could not be precisely estimated, but was believed to be within the range of 32 000 t to 38 500 t. In 2003, a fifteen year rebuilding plan was implemented by Fisheries Commission for this stock (FC Doc. 03/13). Though much lower than values of the early 2000s, estimated catch over 2004-2010 has exceeded the TAC by considerable margins. TAC over-runs have ranged from 22%-64%, despite considerable reductions in effort. The STACFIS estimate of catch for 2010 was 26 170 t (64% over-run). In 2010, Fisheries Commission implemented a survey-based harvest control rule (FC Doc. 10/12) to generate annual TACs over at least 2011-2014. In 2013 Fisheries Commission extended this management approach to set the TACs for 2015 – 2017 (FC Doc. 13/23). STACFIS could not estimate total catches for 2011-2014. STACFIS examined trends in effort as estimated from VMS data. Considering that catch per unit effort has remained relatively high over this period, the observed declines in effort from 2010 to 2014 were not sufficient to explain the apparent decline in the catch estimated by STACFIS in 2010 and reported STATLANT catch for 2014. Therefore STATLANT catch was not accepted as an estimate of catch on this stock in 2014.

	2006	2007	2008	2009	2010	2011	2012	2013	2014	2015

Recent catches and TACs ('000 t) are as follows:

na – not available

¹ – TAC generated from HCR

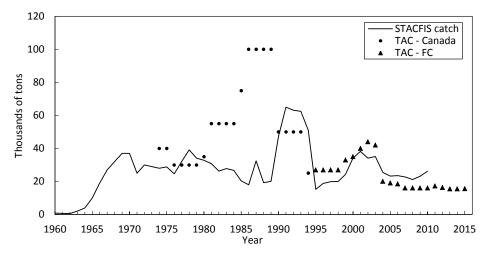

Fig. 20.1. Greenland halibut in Subarea 2 + Divs. 3KLMNO: TACs and STACFIS catches.

b) Input Data

Standardized estimates of CPUE were available from fisheries conducted by EU- Spain and EU-Portugal. Abundance and biomass indices were available from research vessel surveys by Canada in Divs. 2+3KLMNO (1978-2014), EU in Div. 3M (1988-2014) and EU-Spain in Divs. 3NO (1995-2014). Commercial catch-at-age data were available from 1975-2010 but were not compiled for 2011, 2012, 2013 or 2014 because STACFIS could not estimate total catch.

i) Commercial fishery data

Catch and effort. Analyses of otter trawl catch rates from Canadian vessels operating inside of the Canadian 200 mile limit indicated a general decline from the mid-1980s to the mid-1990s. The 2010 – 2012 estimates of standardized CPUE for Canadian otter-trawlers decreased substantially from the 2007-2009 levels. The Canadian CPUE series was not updated since 2012.

Analyses of catch-rates of Portuguese otter trawlers fishing in the NRA of Divs. 3LMNO over 1988-2014 (SCS Doc. 15/06) show that the CPUE has been variable but at a high level 2006.

Analyses of data from the Spanish fishery show that the CPUE has been variable but at a high level since 2006 (SCS Doc. 15/05).

In general, for the Russian fishery, the catch rate per fishing vessel day in the area ranged from 1.0 t to 18.8 t and averaged 9.2 t per fishing vessel day and 0.54 t per hour of hauling (SCS Doc 15/07).

A comparison of the available standardized CPUE estimates from the Canadian, Spanish and Portuguese fleets indicates consistency in the timing and relative magnitude of change over the 2004-2007 period, but less consistency thereafter (Fig. 20.2). However, CPUE for all three countries is higher from 2007-2012 than in the period of the 1990s to the mid 2000s.

. A A

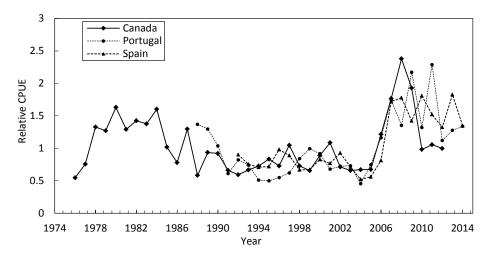

Fig. 20.2 Greenland halibut in Subarea 2 + Divs. 3KLMNO: standardized CPUE from Canadian, Portuguese and Spanish trawlers. (Each standardized CPUE series is scaled to its 1992-2012 average.)

Commercial catch per unit effort for Greenland halibut in Subarea 2 and Divs. 3KLMNO is a measure of fishery performance. STACFIS previously recognized that trends in CPUE should not be used as indices of the trends in the stock. It is possible that by concentration of effort and/or concentration of Greenland halibut, commercial catch rates may remain stable or even increase as the stock declines.

Catch-at-age and mean weights-at-age. Length samples of the 2014 fishery were provided by EU-Spain, EU-Portugal, EU-Estonia, and Russia. Aging information was available for Spanish fisheries. STACFIS could not estimate total catch for 2011-2014, therefore the catch-at-age was not calculated.

ii) Research survey data

STACFIS reiterated that most research vessel survey series providing information on the abundance of Greenland halibut are deficient in various ways and to varying degrees. Variation in divisional and depth coverage creates problems in comparing results of different years (SCR Doc. 12/19). A single survey series which covers the entire stock area is not available. A subset of standardized (depth and area) stratified random survey indices have been used to monitor trends in resource status, and are described below.

Canadian stratified-random autumn surveys in Divs. 2J and 3K. The Canadian autumn Divs. 2J3K survey index provides the longest time-series of abundance and biomass indices (Fig. 20.3) for this resource (SCR Doc. 15/41). Biomass declined from relatively high estimates of the early 1980s to reach an all-time low in 1992. The index increased substantially due to the abundant 1993-1995 year-classes, but this increase was not sustained, with declines over 1999-2002. The index has increased substantially since 2010 to levels near those of the early part of the time series. Mean numbers per tow were stable through the 1980s, but increased substantially in the mid-1990s, again due to the presence of the 1993-1995 year-classes. After this, abundance declined to the late 1990s and had been relatively stable except for the decline in 2005. Following improved estimates of abundance in 2010 and 2011, the 2012 to 2014 indices are considerably lower. The number of age 1-4 is below the series average in 2012-2014.

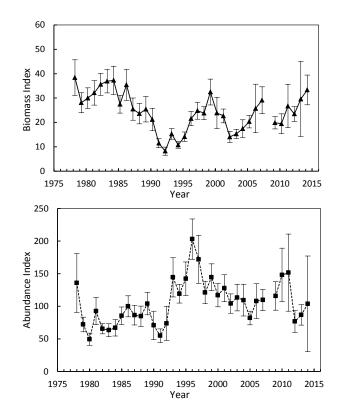

Fig. 20.3. Greenland halibut in Subarea 2 + Divs. 3KLMNO: biomass and abundance indices (with 95% CI) from Canadian autumn surveys in Divs. 2J and 3K. The 2008 survey was not completed.

Canadian stratified-random spring surveys in Divs. 3LNO. Abundance and biomass indices from the Canadian spring surveys in Divs. 3LNO (Fig. 20.4) declined from relatively high values in the late 1990s and has been relatively low in most years thereafter. In 2013 and 2014, both abundance and biomass were below the time-series average. The abundance of recruits (ages 1-4) in 2013 and 2014 is below the time series average.

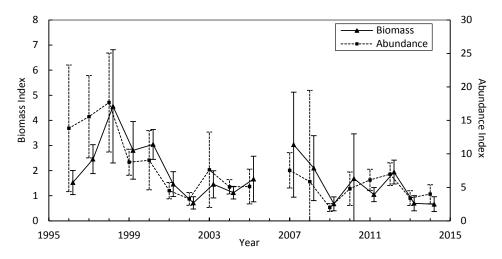

Fig. 20.4. Greenland halibut in Subarea 2 + Divs. 3KLMNO: biomass and abundance indices (with 95% CI) from Canadian spring surveys in Divs. 3LNO.

EU stratified-random surveys in Div. 3M (Flemish Cap). Surveys conducted by the EU in Div. 3M during summer (SCR Doc.15/17) indicate that the Greenland halibut biomass index in depths to 730 m, increased in the 1988 to 1998 period (Fig. 20.5) to a maximum value in 1998. This biomass index declined continually over 1998-2002. The 2002 - 2008 results were relatively stable, with the exception of an anomalously low value in 2003. From 2009 to 2013 the index decreased to its lowest observed value. The index increased in 2014 but remained well below the series average. The Flemish Cap survey was extended to cover depths down to 1 460 m beginning in 2004. Biomass estimates over the full depth range doubled over 2005-2008 but declined thereafter. The 2012 and 2013 estimates are below the time-series average, while the 2014 estimate increased to around the series average. From 2007-2014, recruitment indices (ages 1-4) from this survey (both over the shallower 0-730 m portion and the total 0 – 1 460 m) are below average.

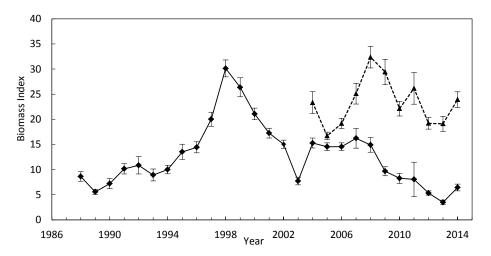

Fig. 20.5. Greenland halibut in SA 2 + Divs. 3KLMNO: Biomass index (± 1 S.E.) from EU Flemish Cap surveys in Div. 3M. Solid line: biomass index for depths <730 m. Dashed line: biomass index for all depths <1 460 m.

EU-Spain stratified-random surveys in NAFO Regulatory Area of Divs. 3LNO. The biomass index for survey of the NRA in Divs. 3NO (SCR Doc. 15/07) generally declined over 1999 to 2006 (Fig. 20.6) but increased four-fold over 2006-2009. The survey index in 2013 and 2014 is below average. The biomass index for the survey of the NRA in Div. 3L (SCR Doc. 15/19) increased from 2004 to 2008. After declining to lower levels in 2011 and 2012 it has increased in 2014 to be equal to the series high.

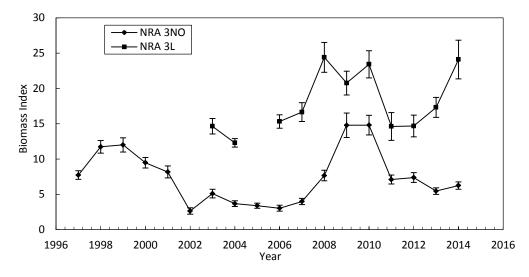

Fig. 20.6. Greenland halibut in SA 2 + Divs. 3KLMNO: biomass index (±1 SE) from EU-Spain spring surveys in the NRA of Divs. 3NO and Div. 3L.

Summary of research survey data trends. These surveys provide coverage of the majority of the spatial distribution of the stock and the area from which the majority of catches are taken. Over 1995-2003, indices from the majority of the surveys generally provided a consistent signal in stock biomass (Fig. 20.7). Results since 2004 show greater divergence which complicates interpretation of overall status. The Canadian autumn 2J3K survey has increased since 2010 to the highest level since 1995. The EU survey of 3M to 1 400 m has been variable with little overall trend since 2004. The Canadian spring survey of 3LNO was at a very low level in 2013 and 2014, equal to the lowest observed. The survey by Spain in 3NO has declined since the high levels of 2010. After decreasing from 2008 to 2011 the survey by Spain in 3L increased from 2012 to 2014 to a level equal to the series high.

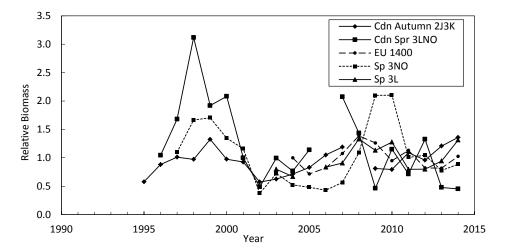

Fig. 20.7. Greenland halibut in SA 2 + Divs. 3KLMNO: Relative biomass indices from Canadian autumn surveys in Divs. 2J3K, Canadian spring surveys in Divs. 3LNO, EU survey of Flemish Cap, and EU-Spain surveys of the NRA of Divs. 3NO. Each series is scaled to its 2004-2014 average.

c) Assessment results

Biomass: Survey data from 2010-2014 are variable which complicates the interpretation of overall status. The Canadian autumn 2J3K survey has increased since 2010 to the highest level since 1995. The EU survey of 3M to 1 400 m has been variable with little overall trend since 2004. The Canadian spring survey of 3LNO was at a very low level in 2013 and 2014, equal to the lowest observed. The survey by Spain in 3NO has declined since the high levels of 2010. The survey by Spain in 3L increased from 2012 to 2014 to a level equal to the series high.

Recruitment: Results of Canadian surveys and the EU Flemish Cap survey indicate that recruitment (ages 1-4) was below average in 2013 and 2014.

Fishing Mortality: Unknown, as estimates of total catch were unavailable.

State of the stock: Survey results in recent years show greater divergence which complicates interpretation of overall status. Two of the three indices used in the HCR have declined while one has increased, in combination resulting in the perception of an overall decline over the last 5 years.

d) Reference Points

i) Precautionary approach reference points

Precautionary approach reference points have not been determined for this stock at this time.

ii) Yield per recruit reference points

Yield per recruit reference points were estimated in 2011. F_{max} was computed to be 0.41 and $F_{0.1}$ was 0.22.

e) **Research recommendations**

STACFIS **recommended** that methods for estimating catch for 2011-2014 be explored for Greenland Halibut in SA 2 + Divs. 3KLMNO, including where ever possible the utility of using effort in conjunction with estimates of catch per unit effort.

This stock will next be assessed in June 2016.

21. Northern Shortfin Squid (Illex illecebrosus) in SAs 3+4

Interim Monitoring Report (SCR Docs. 98/59; 98/75; 02/56; 13/31; SCS Docs. 15/08, 09)

a) Introduction

The species has a lifespan of less than one year and is considered a single stock throughout Subareas 3 through 6. However, the Subareas 3+4 and Subareas 5+6 stock components are assessed and managed separately by NAFO and the U.S. Mid-Atlantic Fishery Management Council, respectively. Distribution, growth rates and recruitment of this highly migratory species are primarily influenced by oceanographic conditions which, when favorable, may lead to high productivity periods. The stock assessment is data-poor. Indices of relative biomass and mean body size, computed using data from the Divs. 4VWX surveys conducted during July by Canada, were used to assess whether the Subareas 3+4 stock component was at a low or high productivity level during the previous year. Stock biomass projections are not currently possible. Relative fishing mortality indices, computed as the Subareas 3+4 nominal catch divided by the Divs. 4VWX biomass ratio, are also used to assess stock status. Based on the trends in these indices, the Subareas 3+4 stock component was in a low productivity period during 1982-2013.

Since 1999, there has been no directed fishery for *Illex* in Subarea 4 and most of the catches from Subareas 3+4, during 1999-2011, were from the Subarea 3 inshore jig fishery. There were no catches from Subarea 3 during 2013 and 2014. During 2004-2011, catches from Subareas 3+4 were low during most years (average = 1 485 t), compared to catches during 1976-1981 (average = 80 645 t), and ranged between about 120 t in 2010 to about 7 000 t in 2006 (Fig. 21.1). Catches in Subareas 3+4 have been less than 50 t since 2012 and reached the lowest level in the time series (since 1953) during 2014 (21 t).

	2006	2007	2008	2009	2010	2011	2012	2013	2014	2015
TAC SA 3+4	34	34	34	34	34	34	34	34	34	34
STATLANT 21 SA 3+4	7.0 ¹	0.21	0.5	0.7	0.1^{1}	0.1^{1}	< 0.11	< 0.11	0	
STATLANT 21 SA 5+6 ²										
STACFIS SA 3+4	7.0	0.2	0.5	0.7	0.1	0.1	<0.1	< 0.1	< 0.1	
STACFIS SA 5+6	14.0	9.0	15.9	18.4	15.8	18.8	11.7	3.8	8.8	
STACFIS Total SA 3-6	21.0	9.2	16.4	19.1	15.9	18.9	11.7	3.8	8.8	

Recent catches and TACs ('000 t) are as follows:

¹ Includes amounts (< 0.1 t to 22 t during 2006-2011 and 0.2 t to 5 t during 2012-2014) reported as 'Unspecified Squid' from Subarea 4 which were likely *I. illecebrosus*.

² Catches from Subareas 5+6 are included because there is no basis for considering separate stocks in Subareas 3+4 and Subareas 5+6.

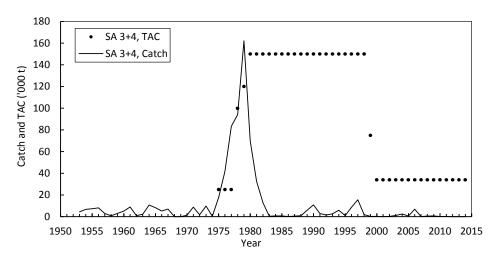

Fig. 21.1. Northern shortfin squid in Subareas 3+4: nominal catches and TACs.

b) Data Overview

The July relative biomass indices, derived using data from the Canadian surveys conducted in Divs. 4VWX, are assumed to represent relative biomass levels at the start to the fisheries in SA 3+4. Biomass indices have fluctuated widely since 2003 but generally declined after 2004, from a level near the mean of the high productivity period to below the mean of the low productivity period in 2010. Thereafter, biomass indices declined to the lowest level in the time series during 2013 (Fig. 21.2). The 2014 index (1.11) was slightly higher than during 2013 but was still well below the mean (2.83) of the low productivity period.

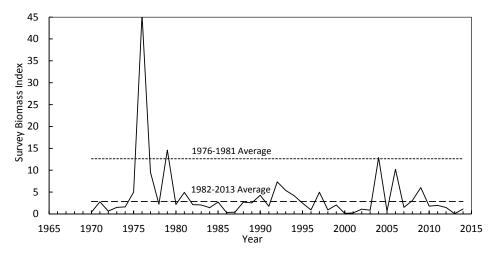

Fig. 21.2. Northern shortfin squid in Subareas 3+4: survey biomass indices from the July survey in Divs. 4VWX.

Squid are heavier during high productivity periods. Since 1982, mean body weights of squid caught during the July Divs. 4VWX surveys have fluctuated widely around the mean for the 1982-2013 low productivity period (79 g, Fig. 21.3). After reaching a low productivity period peak of 137 g in 2006, mean body weights gradually declined to the fourth lowest level of the time series in 2013 (42 g). During 2014, mean body weight (110 g) increased to the highest level since 2006 but remained well below the high productivity period mean (150 g).

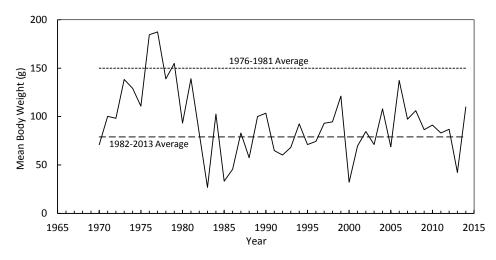

Fig. 21.3. Northern shortfin squid in Subareas 3+4: mean body weights of squid from the July survey in Divs. 4VWX.

Catch/biomass ratios (SA 3+4 nominal catch/Divs. 4VWX July survey biomass index)/10 000 have been well below the 1982-2013 mean (0.13) during most years since 2001 and the ratio was < 0.01 in 2014 (Fig. 21.4).

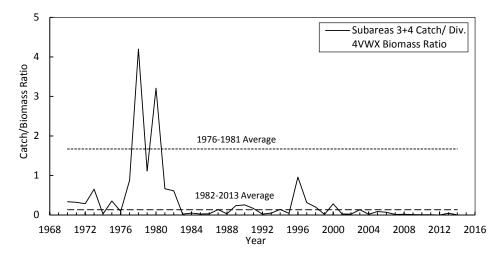

Fig. 21.4. Northern shortfin squid in Subareas 3+4: catch/biomass ratios.

c) **Conclusion**

During 2014, the biomass index from the July Divs. 4VWX survey was below the average for the 1982-2013 low productivity period and mean body weight (110 g) was above the 1982-2013 average (79 g) but below the average for the high productivity period (150 g). Catch/biomass ratios have been well below the low productivity period mean during most years since 2001. Thus, in 2014, the stock remained in a state of low productivity.

The next full assessment of the stock is scheduled for 2016.

d) Research Recommendation

In 2013, STACFIS **recommended** that gear/vessel conversion factors be computed to standardize the 1970-2003 relative abundance and biomass indices from the July Divs. 4VWX surveys.

STATUS: No progress.

IV. STOCKS UNDER A MANAGEMENT STRATEGY EVALUATION

1. Greenland halibut in SA2 and Divs. 3KLMNO

This stock is taken under D. Widely Distributed Stocks: SA 2, SA 3 and SA 4.

V. OTHER MATTERS

1. FIRMS Classification for NAFO Stocks

STACFIS reviewed the assessments of stocks managed by NAFO in June 2015. STACFIS reiterates that the Stock Classification system is not intended as a means to convey the scientific advice to Fisheries Commission, and should not be used as such. Its purpose is to respond to a request by FIRMS to provide such a classification for their purposes. The category choices do not fully describe the status of some stocks. Scientific advice to the Fisheries Commission is to be found in the Scientific Council report in the summary sheet for each stock.

Stock Size	Fishing Mortality			
(incl. structure)	None-Low	Moderate	High	Unknown
Virgin-Large	3LNO Yellowtail flounder			
Intermediate	3M Redfish ³ 3LN Redfish 3NO Witch flounder	SA0+1 Northern shrimp ¹ DS Northern shrimp ¹ 0&1A Offsh. & 1B–1F Greenland halibut	3M Cod	Greenland halibut in Uummannaq ² Greenland halibut in Upernavik ² Greenland halibut in Disko Bay ² SA1 American Plaice SA1 Spotted Wolffish
Small	SA3+4 Northern shortfin squid 3NOPs White hake			3LNOPs Thorny skate SA2+3KLMNO Greenland halibut
Depleted	3M American plaice 3LNO American plaice 2J3KL Witch flounder 3NO Cod 3M Northern shrimp ^{1,3} 3LNO Northern shrimp ¹			SA1 Redfish SA0+1 Roundnose grenadier SA1 Atlantic Wolffish
Unknown	SA2+3 Roughhead grenadier 3NO Capelin 30 Redfish			SA2+3 Roundnose grenadier

¹ Shrimp will be re-assessed in September 2015

² Assessed as Greenland halibut in Div. 1A inshore

³ Fishing mortality may not be the main driver of biomass for Div. 3M Shrimp and Redfish

2. Other Business

a) Invited Speaker

STACFIS discussed the plan to have an invited speaker at the June 2015 meeting. Unfortunately none of the candidates approached were available to attend. STACFIS reiterates its support for this programme. Invitations will be extended to enable a speaker to attend the June 2016 meeting.

VI. ADJOURNMENT

STACFIS Chair thanked the Designated Experts for their competence and very hard work and the Secretariat for its great support. The Chair also noted the contributions of Designated Reviewers in providing detailed reviews of interim monitoring reports. The STACFIS Chair also thanked the Chair of Scientific Council, and the Scientific Council Coordinator for their support and help. The meeting was adjourned at 1300 on 11 June 2015.

Report of the NAFO Joint Fisheries Commission–Scientific Council Working Group on Ecosystem Approach Framework to Fisheries (WG-EAFFM)

15–17 July 2015 Halifax, Nova Scotia, Canada

1. Opening

The meeting was called to order at 1000 hrs on 15 July 2015 by Andrew Kenny (EU). He offered apologies on behalf of the other co-Chair, Robert Day (Canada), who was unable to attend the meeting.

Representatives from Canada, Denmark (in respect of the Faroe Islands and Greenland) (DFG), European Union (EU), Iceland, Japan, Norway, the Russian Federation, and the USA were in attendance. The Scientific Council was represented by the SC Vice-Chair. Observers from Ecology Action Centre and World Wildlife Fund Canada were also in attendance (Annex 1).

22. Appointment of Rapporteur

The Fisheries Commission (FC) and Scientific Council (SC) Coordinators, Ricardo Federizon and Neil Campbell, were appointed as co-Rapporteurs.

23. Adoption of Agenda

With the addition under other matters of two items regarding the "Coral and Sponge Identification Guide – NAFO Area" for observers, and the review clause for Chapter 2 (Article 24) of the NCEM, the agenda was adopted (Annex 2).

24. Consideration of SC advice from 2015

The SC vice-Chair, Kathy Sosebee (USA) presented an overview of the SC response (formulated in June 2015) to the FC Requests for Advice (formulated in September 2014) on topics relevant to the agenda of this Working Group (WG) (Annex 3). The SC Response covers topics including Significant Adverse Impact (SAI) on Vulnerable Marine Ecosystem (VME) elements and species, impacts of removing candidate VME closures from survey design, impacts other than fishing in the NAFO Regulatory Area (NRA), and impacts of mid-water trawls on VME indicator species. Details of the SC advice are documented in SCS Doc. 15/12.

a) Development of work on Significant Adverse Impacts in support of workplan for assessment of bottom fisheries in 2016

The presiding Chair elaborated on the SAI advice (Annex 4). The WG was informed that the SC's work plan for the assessment of bottom fishing activities by 2016 is progressing as scheduled, and development of a template for the assessment report is underway. An important addition to the template is a review of the current fisheries which summarises the spatial extent of the fisheries (see slides 5-6 in Annex 4). In its approach to assessing SAI, the first three of the FAO criteria (as defined in paragraph 18 of the 2009 FAO *International Guidelines for the Management of Deep-Sea Fisheries in the High Seas*) are being analysed, namely; intensity/severity of impact, spatial extent of impact, and sensitivity/vulnerability of ecosystem. The subsequent three criteria (recovery, function, and duration) relate to functionality of the ecosystem, rather than the impact of fishing on the structure of the benthic fauna and habitat. They will be addressed at a later stage.

The WG noted the preliminary nature of the work presented and thanked SC for the extensive effort which has gone into the assessment to date. It was noted that benthic fisheries for shellfish on the tail of the Bank were included in the preliminary assessment. It was, agreed that these fisheries should be excluded from further analysis as NAFO has no management jurisdiction in this regard. It was also noted that mid-water trawl fisheries should not be included in the description or the analysis of bottom fisheries.

It was noted that 46% of the area of the fisheries closures (as referred to in NCEM Article 17.5) fall outside the footprint (as referred to in NCEM Article 16) and were therefore not at risk of SAI. The remaining 54% of the area of the fisheries closures (within the footprint), represents 6% of the footprint closed to bottom fishing to protect VME. Through a combination of analysing VMS data (2008–2014) and VME indicator

species biomass for sponge, seapen and large gorgonian, the area of VME (outside current closures) likely to be impacted by bottom fishing can be estimated (see Table 1). It was noted that an impact on VME does not necessarily mean it is significant. For example if only 1% of the VME habitat has been impacted it would be assessed as not significant. For illustrative purposes, it was noted that under the EU Habitats Directive⁶ some assessments of designated habitat features 25% of the area being impacted as the criteria to determine when the loss of habitat would result in a feature being in an 'unfavourable' state. If this approach were to be applied, the provisional assessment of area of VMEs potentially impacted by past activities for each of the assessed VME types fall below this value and the assessment would therefore conclude that there is no SAI to report. However, there could be SAI in the future and therefore possible management measures to minimize the risk of future SAI should be considered in the assessment. In addition, VMEs outside current closures could be under a potential risk of impact should fishing patterns change and in the absence of suitable mitigation measures. It was noted that findings presented (Annex 4 – Slide 13) are preliminary and did not pre-judge the ongoing assessment of SAI to be finalized in 2016.

Table 6.Area (km²) of VME inside and outside current fishery exclusion zones closures. "Cut-off" is
the value of VME species biomass which distinguishes between areas of VME which are at
potential risk of SAI *versus* areas of VME which have been subject to possible past or historic
SAI. The "cut-off" values between the two conditions of at risk and past SAI are described
and defined in SCS Doc. 14-23 and SCS Doc. 15-12.

	Sponges	%	Seapens	%	Coral	%	Notes
Total area of VME	22,439	100	6,983	100	3,725	100	
Total area of VME INSIDE Closed Area	8,042	36	1094	16	1,992	53	Not at risk of SAI
Total area of VME OUTSIDE Closed Area	14,397	64	5889	84	1,733	47	Total area of potential SAI
Area of VME OUTSIDE Closure, above "cut-off"	4,351	30	1,484	25	668	39	"historic" or "past" SAI
Area of VME OUTSIDE Closure, below "cut-off"	10,045	70	4,404	75	1,064	61	At present- day risk of SAI
Proportion of total VME subject to "historic" or "past" SAI	-	20	-	21	-	16	
Proportion of total VME at risk of present-day SAI	-	45	-	63	-	31	

It was felt that the understanding of the SAI analysis would be improved if SC were to compile, define and agree on terminology used in the reassessment of bottom fisheries, with particular emphasis on the definitions of SAI. It was further suggested that the evaluation of SAI would be improved if in addition to considering the VME areas derived from the kernel density analysis, biomass distributions of VME indicator taxa were also taken into account, e.g. assess the proportion of biomass within and outside current closures. In addition, it was suggested that the VME kernel density analysis polygon boundaries could be refined by taking into account current understanding of VME species distribution patterns in relation to environmental variables.

⁶ Council Directive 92/43/EEC of 21 May 1992 on the conservation of natural habitats and of wild fauna and flora: <u>http://eur-lex.europa.eu/legal-content/EN/TXT/?uri=CELEX:01992L0043-20070101</u>

b) Removal of closed areas from scientific surveys

The SC vice-Chair presented the work of SC and the Secretariat on the impacts of removing the closed areas from the survey design for relevant stock surveys. There has been limited progress; however, work is ongoing to quantify the overlap between VME protection areas and RV surveys. It was noted that removing these areas from the survey design could have implications for survey estimates. However, the WG urges SC to consider options to expedite the assessment process. Furthermore, it was suggested that the dialogue between the FC and SC Chairs on priorities and workload should take place at the earliest opportunity, with this task having increased priority.

c) Impact of activities other than fishing on fish stocks and biodiversity in the NRA

The SC vice-Chair presented the results of the literature review of potential impact from activities other than fishing on fish stocks and biodiversity in the NRA. It was noted that there was limited expertise currently available in the SC on many of these issues. It was recognized that NAFO is not the competent authority for the management of many of these activities. Prioritization of these other activities in terms of their likelihood of impacting upon fish stocks in the northwest Atlantic was mentioned as a possible way to reduce the scale of the work without any conclusion being reached on the way forward. One CP noted that in the SC's response oil and gas activities contained the biggest number of stressors, potential effects and risks; oil and gas activities are also explicitly mentioned as part of the Ecosystem Approach Roadmap (Fig. 1). It was also noted that in the northeast Atlantic, non-binding discussion between NEAFC, OSPAR, and the International Seabed Authority takes place, and that this could serve as a model for dialogue in the NAFO context.

On a related note, the Executive Secretary informed the WG that Canada has provided an extensive proposal regarding a mechanism for exchange of information to avoid overlapping and mitigate potential conflict between fisheries and hydrocarbon activity. This was recently circulated to Contracting Parties and Chairs.

d) Impacts of mid-water trawls on benthic VME indicator species

SC focused its response to this request on potential impacts of midwater trawling around seamounts, and advised that midwater trawls around seamounts have the potential to have bottom contact and therefore present a risk of causing SAI. This risk is lower than for a bottom trawl.

SC recommended that midwater trawl fisheries on seamounts report bycatch of all VME indicator species bycatch, regardless of the amount caught. This recommendation was endorsed by the WG. It was requested that at its future meeting(s) that the WG review any available information on bycatch resulting from this enhanced reporting requirement.

25. Consideration of NCEM Articles 17.1 - 17.3 (Seamounts)

At the 2014 Annual Meeting, FC referred the issue of exploratory fisheries in seamount areas to the WG for further consideration (FC Doc. 14/35).

It was noted that two CPs had operated fisheries in these areas over a long period. Current seamount closures in NAFO provide a level of protection identical to that provided by other areas outside the fishing footprint Opinions within the WG as to the nature of the risk presented by midwater trawls to VME indicator species in NAFO varied. A range of possible ways to proceed was discussed including: *i*. to leave the current situation unchanged, *ii*. to remove the "seamount closures" from the CEM, recognizing that the protection they once provided is now applied to the entire NAFO Regulatory Area outside the footprint, or *iii*. to further control bottom fishing within the seamount areas, for example by removing the provision for exploratory bottom fisheries from Article 17. This third course of action was endorsed by the WG, as was a suggestion to develop a mid-water gear design, to be applied to seamount areas, and ensuring very minimal or no risk of bottom impacts (e.g. use of gear with no discs, bobbins, etc).

It was considered and agreed that it was not necessary to redefine midwater trawls as a bottom gear, but to recognize that midwater trawls in certain defined areas (seamounts) and fisheries (alfonsino) could contact the bottom (see Section 4d). A consensus formed that midwater trawl fisheries in seamounts should be subject to current gear provisions used for midwater trawls for redfish. With this agreement, the need for a definition of midwater trawling that would apply to seamount fisheries was also recognized.

Further, taking into account SC advice which highlighted the potential risk of SAI, the WG agreed to eliminate the provision for exploratory bottom fisheries in the NAFO seamount areas until 2020 when all VME provisions will be subject to review by FC.

26. Discussion of ongoing matters

a) Status of Candidate VME areas 13 and 14 (eastern Flemish Cap)

and

b) Status of Div. 30 Coral Closure

and

c) Significant concentrations of VME indicator species on Tail of the Bank (Div. 3N)

There was no new information or evidence to elaborate the assessment of these areas as reported in the previous meeting of this WG (FC-SC Doc. 14-03), however it was noted that data from a Canadian VME survey in 2015, as well as additional bottom trawl survey bycatch data from the EU-Spain survey, would be available to SC Working Group on Ecosystem Science and Assessment (WG-ESA) later in 2015. It was therefore requested that these topics be retained on the agenda for future discussion pending analysis of new data.

27. Implementation of the "Ecosystem Approach"

a) Review of the "Roadmap to an Ecosystem Approach"

The co-Chair of WG-ESA Mariano Koen-Alonso (Canada) presented a progress report on the work done by SC in further developing the Roadmap (Annex 5), focusing on those elements that SC considered advanced enough to start the discussion of their potential implications and avenues for implementation. These elements included (1) the definition of spatial scales considered relevant and practical for devising ecosystem-level summaries and management plans, (2) the delineation of Ecosystem Production Units (EPUs) that SC endorsed as candidate ecosystem-level management units for pilot implementations of EAF, and (3) the results from Ecosystem Production Potential models for some of these areas. These models provide estimates of Fisheries Production Potential that can serve as basis for developing "Total Catch Ceilings" (the maximum catch allowed across all species in an Ecosystem-level management unit).

The WG broadly welcomed this work, acknowledged that this being the first time these types of analyses have been presented at the WG, and indicated that more time was needed to reflect on them and further consider their management implications and potential mechanisms for implementation. The WG encouraged continued progress toward further developing these analyses and tools towards practical management applications to maintain momentum in this area.

The WG recognized that, as work on the implementation of the roadmap progresses, priorities and tasks may change over time. The WG updated the set of tasks and priorities to be progressed over the next year (Fig. 1). Updates reflect that the review of fishery closures was completed last year and the focus for 2015-2016 is the re-assessment of bottom fisheries.

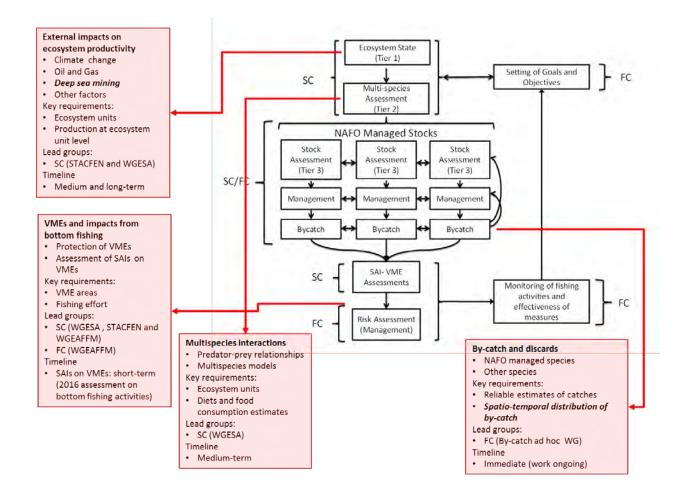

Fig. 1. Updated Workplan and Prioritization of the EAF Roadmap addressing other factors impacting the ecosystem (changes indicated in italic-bold text).

b) Addressing other factors impacting the ecosystem

The WG thanked SC for its thorough overview. It was recognized that if NAFO wishes to give further consideration to any of these issues, it will have to be in partnership with specific competent bodies. The list prepared by SC serves as a useful scoping document, and attempts could be made to prioritize these issues and identify relevant partners. To illustrate, it was noted that deep-sea mining exploration licenses are being issued at the mid-Atlantic ridge regions. Should interest expand to the NAFO Regulatory Area then engagement with the International Seabed Authority might be appropriate.

c) Future direction of FC-SC WG-EAFFM

Participants considered the future role of the WG. Noting the strong synergy between the *ad hoc* FC Working Group on Bycatch and Discards (WG-BDS), the work being carried out on bycatch in WG-ESA and the role of the FC-SC WG-EAFFM, it was felt that more effective coordination and integration of the outputs and discussion held by these two groups could be achieved so as to avoid duplication of effort. It was noted a similar discussion had taken place in the *ad hoc* WG-BDS which met immediately before this WG, it was therefore agreed to await the outcome of recommendations arising from that *ad hoc* group, as they met first.

28. Other matters

a) Coral and Sponge Identification Guide - NAFO Area

Progress by the Secretariat and members of WG-ESA on updating the Coral and Sponge Identification Guide in the NAFO Area to produce a single volume containing all NAFO's recognized VME Indicator Species was

welcomed. Further areas for development, noting the US guides to bycatch species, the FAO Smartforms initiative and the WWF "app", were discussed.

b) Wording of NCEM Article 24

An outdated reference in Chapter II, Article 24 was noted. A recommendation was made to Fisheries Commission to update this Article and proposed a full review of the VME measures in 2020.

29. Recommendations to forward to the Fisheries Commission and Scientific Council

The Working Group **recommends**:

In relation to Progress of the Workplan on SAI in support of reassessment of bottom fisheries in 2016:

- that Scientific Council should take into account the protection afforded to VME areas outside the NAFO fisheries footprint in the calculation of the VME area and biomass at risk of bottom fishing impact;
- 2. that Scientific Council refine VME kernel density analysis polygon boundaries, taking into account current understanding of distribution patterns in relation to environmental variables.

In relation to removal of closed areas from scientific surveys:

3. that Scientific Council considers options to expedite a risk assessment of trawl surveys impact on VME in closed areas, and the effect of excluding surveys from these areas on stock assessments.

In relation to activities other than fishing:

4. that Fisheries Commission request the General Council to identify other international organizations (e.g. International Maritime Organization, International Seabed Authority) with areas of mutual interest and instruct the Secretariat to explore the establishment of mechanisms for dialogue and engagement.

In relation to impacts of mid-water trawls on benthic VME indicator species and habitats:

5. that Fisheries Commission or STACTIC amend the NCEM to broaden the scope of application of the meaning of 'midwater trawl', as referred to in Article 13.2.f, to apply to midwater trawls in the seamount areas referred to in Article 17.

In relation to NCEM Articles 17.1 - 17.3 (Seamounts):

- 6. that Fisheries Commission revise Article 17 to remove the possibility of exploratory bottom fishing in seamount areas;
- 7. that Fisheries Commission revise NCEM to require reporting of all quantities of all VME indicator taxa catches (Annex I.E.VI), in seamount areas (Article 17) for instance through logbooks or observer reports.

In relation to Other matters:

- 8. that Scientific Council consider widening the scope of the NAFO coral and sponge identification guides to include other relevant species on seamounts.
- 9. that Fisheries Commission revise Article 24 as follows:

"The provisions of this Chapter shall be reviewed by the Fisheries Commission at its Annual Meeting no later than 2020".

These recommendations will be presented to FC and SC at the 2015 Annual Meeting for consideration and adoption.

2. Adoption of the report

It was agreed that the text of the recommendations to Fisheries Commission and Scientific Council agreed in plenary was considered final. A first draft of the remainder of the report would be written up by the Secretariat and circulated firstly to the Chair and then to Contracting Parties in the days following the meeting.

30. Adjournment

The meeting was adjourned at 1100 hrs on 17 July 2015. The Chair thanked participants for their positive approach and engagement in the meeting, thanked the Secretariat for their support and hospitality, and wished participants a safe journey home

SC 9-16 Sep 2015

Report of the Scientific Council Meeting 9-16 September 2015

Chair: Don Stansbury

Rapporteur: Neil Campbell

I. PLENARY SESSIONS

The Scientific Council met at the Northwest Atlantic Fisheries Centre, St John's, Newfoundland during 9-16 September 2015, to consider the various matters in its Agenda. Representatives attended from Canada, Denmark (Greenland), European Union (Denmark, Estonia, Spain and Sweden), Iceland, Norway and the United States of America. The Scientific Council Coordinator was in attendance.

The Executive Committee met at 0900 to discuss a plan of work. The opening session of the Council was called to order at 0930 hours on 9 September 2015.

The Chair welcomed representatives, advisers and experts to the opening session of Scientific Council. The Chair noted that the primary reason for this meeting was to provide advice on shrimp stocks based on the assessments provided by the joint NAFO/ICES *Pandalus* Assessment Group (NIPAG). ICES members of NIPAG were granted observer status at the Scientific Council meeting, and the Chair wished all NIPAG members a productive and successful meeting.

The Scientific Council Coordinator, Neil Campbell, was appointed Rapporteur.

This opening session was adjourned at 1000 hours. Several sessions were held throughout the course of the meeting to deal with specific items on the agenda.

The concluding session was convened at 0900 hours on 16 September 2015. The Council then considered and adopted Sections III.1–4 of the "Report of the NAFO/ICES *Pandalus* Assessment Group" (NAFO SCS Doc. 15/13, ICES CM 2015/ACOM:14). The Council, having considered the results of the assessments of the NAFO stocks, provided advice and recommendations and noted the requests of the Fisheries Commission and Coastal States had been addressed. The Council then considered and adopted its own report of the 10-17 September 2014 meeting.

The meeting adjourned at 1800 hours on 16 September 2015.

The revised Agenda, List of Research (SCR) and Summary (SCS) Documents, and the List of Representatives, Advisers and Experts, are given in Appendix I, II and III, respectively.

II. REVIEW OF RECOMMENDATIONS IN 2014

These were reviewed in the appropriate STACFIS sections below.

III. NAFO/ICES PANDALUS ASSESSMENT GROUP

NIPAG has assessed four stocks of relevance to NAFO: Northern shrimp in Div. 3M, Northern shrimp in Div. 3LNO, Northern shrimp in Subareas 0 and 1, and Northern shrimp in Denmark Strait and off East Greenland. The Scientific Council summary sheets and conclusions for these stocks are presented in Section IV of this report. The recommendations to Fisheries Commission, with respect to stock advice, appear in the summary sheets. The full NIPAG report is available in NAFO SCS Doc. 15/13 and ICES CM 2015/ACOM:14.

IV. FORMULATION OF ADVICE (SEE ANNEXES 1, 2 AND 3)

1. Request from Fisheries Commission

The response of Scientific Council to the Fisheries Commission Request for Advice (Annex 1a) for shrimp in Div. 3M and Div. 3LNO regarding stock assessment (Item 1) is given below.

249

Advice September 2015 for 2016-17

Recommendation

No directed fishery for 2016 and 2017.

Management objectives

No explicit management plan or management objectives defined by Fisheries Commission. General convention objectives (GC Doc. 08-03) are applied. Advice is based on qualitative evaluation of biomass indices in relation to historic levels, and provided in the context of the precautionary approach framework (FC Doc. 04/18).

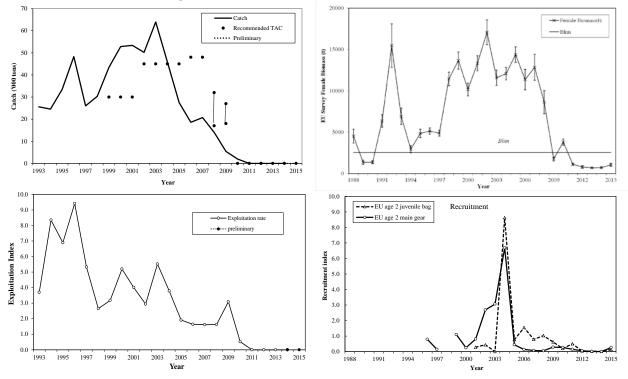

Convention objectives	Status	Comment/consideration		
Restore to or maintain at B_{msy}	0	Stock below B _{lim}		ОК
Eliminate overfishing		No directed fishery		Intermediate
Apply Precautionary Approach	0	<i>B</i> _{lim} defined. No fishing mortality reference point defined	0	Not accomplished
Minimise harmful impacts on living marine resources and ecosystems	•	No directed fishery	0	Unknown
Preserve marine biodiversity	0	Cannot be evaluated		

Management unit

The Northern Shrimp stock on Flemish Cap is considered to be a separate population.

Stock status

Following several years of low recruitment, the spawning stock has declined, and has remained below B_{lim} since 2011. Due to continued poor recruitment there are concerns that the stock will remain at low levels.

Reference points

Scientific Council considers that a female survey biomass index of 15% of its maximum observed level provides a proxy for B_{lim} (2564) (SCS Doc. 04/12).

251

Projections

Quantitative assessment of risk at various catch options is not possible for this stock at this time.

Assessment

No analytical assessment is available. Evaluation of stock status is based upon fishery and research survey data.

This stock is now assessed biennialy. The next full assessment is currently scheduled for 2017.

Human impact

Low fishery related mortality due to moratorium and low bycatch in other fisheries. Other sources (e.g. pollution, shipping, oil-industry) are considered minor.

Biological and Environmental Interactions

The drastic decline of shrimp biomass since 2007 correlates with the increase of the cod stock in Div. 3M. It is uncertain whether this represents a causal relationship and/or the result of an environmental factor.

Results of modelling suggest that, in unexploited conditions, cod would be expected to be a highly dominant component of the system, and high shrimp stock sizes like the ones observed in the 1998 – 2007 period would not be a stable feature in the Flemish Cap.

Fishery

This fishery is effort-regulated. The effort allocations were reduced by 50% in 2010 and a moratorium was imposed in 2011. Catches are expected to be close to zero in 2015.

	2008	2009	2010	2011	2012	2013	2014	2015
NIPAG	13 000	5 000	2 000	0	0	0	0	01
STATLANT 21	13431	5374	1976	0	0	0	0	
Effort (Agreed Days)	10555	10555	5227	0	0	0	0	

Recent catches and agreed effort were as follows:

¹ To September 2015

Effects of the fishery on the ecosystem

No fishery.

Special comments

None

Source of Information

SCR Doc. 15/047

Advice September 2015 for 2016

Recommendation for 2016

No directed fishery as the stock is below B_{lim} .

Management objectives

No explicit management plan or objectives defined by Fisheries Commission. General convention objectives (GC Doc. 08/3) are applied. Advice is based on qualitative evaluation of biomass indices in relation to historic levels, and provided in the context of the precautionary approach framework (FC Doc. 04/18).

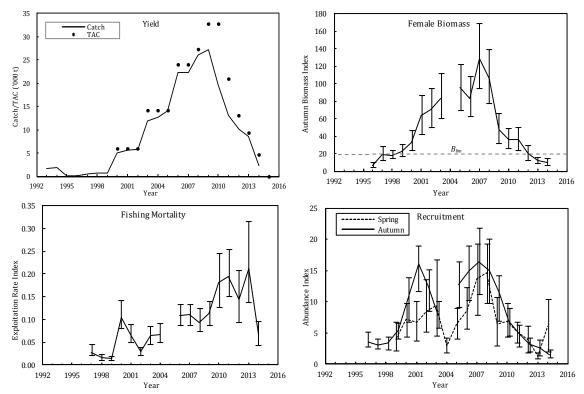

Status	Comment/consideration		
0	Stock below B _{lim}		ОК
	No directed fishery	0	Intermediate
0	<i>B_{lim}</i> is defined. No fishing mortality reference point defined	0	Not accomplished
0	No directed fishery	0	Unknown
0	Cannot be evaluated		
	Status	 Stock below B_{lim} No directed fishery B_{lim} is defined. No fishing mortality reference point defined No directed fishery 	 Stock below B_{lim} No directed fishery B_{lim} is defined. No fishing mortality reference point defined No directed fishery

Management Unit

The stock in Div. 3LNO is assessed and managed as a discrete population (see special comment).

Stock Status

The stock has declined since 2007, and in 2014 the risk of being below B_{lim} is greater than 95%. Given expectations of poor recruitment, the stock is not expected to increase in the near future.

Reference points

Scientific Council considers that a female survey biomass index of 15% of its maximum observed level provides a proxy for B_{lim} (19 330) (SCS Doc. 04/12).

Projections:

Quantitative assessment of risk at various catch options is not possible for this stock at this time.

Assessment

Based upon a qualitative evaluation of trends in stock biomass, fishing mortality proxy and recruitment. Input data are research survey indices and fishery data (NIPAG 2015).

Next full assessment is planned for 2016.

Human impact

Mainly fishery related mortality has been documented. Other sources (e.g. pollution, shipping, oil-industry) are considered minor.

Biological and Environmental Interactions

Both stock development and the rate at which changes might take place can be affected by changes in predation, in particular by cod, which has been estimated to consume large amounts of shrimp. The size of the cod stocks in Div. 2J3KL and Div. 3NO have increased, but remain at low levels . Some other groundfish (e.g. redfish) which consume shrimps are known to have increased, but the impact on the shrimp stock has not been quantified.

Temperature in the stock area has been warming over the past decade. Effects of temperatures on shrimp distribution, recruitment, growth and survival are poorly understood.

Fishery

The fishery, until 2014 was a directed bottom trawl fishery and there is little or no bycatch of shrimp in other trawl fisheries. The fishery in Div. 3LNO is regulated by quota.

	2006	2007	2008	2009	2010	2011	2012	2013	2014	2015
Enacted TAC ¹	24029	24029	27306	32767	32767	20971	13108	9393	4697	ndf
STATLANT 21	22377	22315	26097	27236	19745	13013	10204	8524	2289	
NIPAG ²	25689	23570	25407	25900	20536	12900	10108	8647	2289	

¹ Includes autonomous TAC as set by Denmark (in respect of Faroes and Greenland).

² NIPAG catch estimates have been updated using various data sources (see p. 13, SCR Doc 14/048).

Effects of the fishery on the ecosystem

No specific information available. General impacts of fishing gear on the ecosystem should be considered.

Special Comments

Genetic analysis has been completed. Shrimp in Div. 3LNO are genetically distinct from those in Div. 3M and the Gulf of Maine, but not from those further north. Additional work is ongoing to investigate the contribution of stocks north of Div. 3L to the production of Div. 3LNO shrimp.

Sources of information

SCR Doc. 14/048, 15/048, /055; http://www.dfo-mpo.gc.ca/Library/352955.pdf

SC 9-16 Sep 2015

31. Requests from Coastal States

a) Northern Shrimp in Subarea 1 and Div. 0A

Scientific Council responded:

Northern Shrimp in Subarea 1 and Div. 0A

Advice September 2015 for 2016

Recommendation

Previous work has shown that a maintained mortality risk of 35% is low enough to keep stock levels safely at or above B_{msy} . A catch of 90 000 t in 2016 would entail an estimated mortality risk below 35%. Scientific Council therefore advises that catches in 2016 should not exceed 90 000 t.

255

Management Objectives

Scientific Council is aware of the Greenland management plan for shrimp and of general management objectives specified in the Greenland Fisheries Act; however the contents of these have not been conveyed to the Council. Canada requested Scientific Council to provide advice on this stock within the context of the NAFO Precautionary Approach Framework (SCS Doc. 13/04).

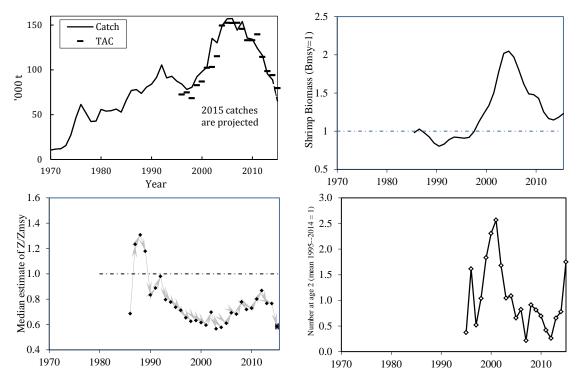

Advice is based on risk analysis coming from a quantitative model, and on qualitative evaluation of biomass and stock-composition indices.

Objective	Status	Comment/consideration		
Apply Precautionary Approach	•	Stock status is both estimated and forecast relative to precautionary reference points	0	OK

Management unit

The stock, considered distinct from all others, is distributed throughout Subarea 1, extends into Div. 0A east of 60°30'W, and is assessed as a single stock.

Stock status

A protracted decline in stock size since 2004 appears to have paused, and large numbers of small shrimps in the 2015 survey show good prospects for recruitment. At end 2015 the stock is expected to be 23% above B_{msy} and the risk of being below B_{lim} (30% of B_{msy}) is very low (<1%).

Reference points

 B_{lim} is 30% of B_{msy} and the limit reference point for mortality is Z_{msy} (FC Doc. 04/18).

Projections

Predicted probabilities of transgressing precautionary reference points in 2016 – 2018 under seven catch options and subject to predation by a cod stock with an effective biomass of 55 Kt (the value for 2015 being 56Kt.).

55 000 t cod	Catch option ('000 tons)									
Risk of:	60	70	75	80	85	90	95	100		
falling below <i>B_{msy}</i> end 2016 (%)	25	25.0	25	26	27	27	27	27		
falling below B_{msy} end 2017 (%)	25	26.0	27	27	28	28	29	30		
falling below B_{msy} end 2018 (%)	26	28	29	30	31	31	32	33		
falling below B_{lim} end 2016 (%)	<5	<5	<5	<5	<5	<5	<5	<5		
falling below B_{lim} end 2017 (%)	<5	<5	<5	<5	<5	<5	<5	<5		
falling below B_{lim} end 2018 (%)	<5	<5	<5	<5	<5	<5	<5	<5		
exceeding Z_{msy} in 2016 (%)	22	25	27	28	31	32	35	37		
exceeding Z_{msy} in 2017 (%)	23	26	28	29	32	33	37	39		
exceeding Z_{msy} in 2018 (%)	24	27	29	31.0	33	35	38	40.0		

Assessment

The analytical assessment was run with the same basic model as in 2011–2014; minor changes in the coding (estimation of parameters of a functional relationship for cod predation; calculation of future mortalities) are described in SCR Doc. 15/49; and with updated data series.

The next assessment is scheduled for 2016.

Human impact

Mortality related to the fishery has been documented. Other human sources (e.g. pollution, shipping, oil-industry) are considered minor.

Biological and Environmental Interactions

Cod is an important predator on shrimps. This assessment incorporates this interaction. Other predation is likely but not explicitly considered. Shrimps might be important predators on, for example, fish eggs and larvae.

Fishery

Shrimps are caught in a directed trawl fishery. Bycatch of fish in the shrimp fishery is around 1% by weight. The fishery is regulated by TAC.

	2008	2009	2010	2011	2012	2013	2014	2015
Enacted TAC ¹	145 717	132 987	132 987	142 597	118 596	102 767	94 140	79 561
STATLANT 21	148 550	133 990	129 179	123 195	115 080	91 802	88 834	-
NIPAG	153 889	135 458	133 990	123 985	115 975	95 380	88 765	65 000 ²

Recent catches and TACs (t) have been as follows:

¹ sum of TACs autonomously set by Canada and Greenland;

² provisional—projected to year end.

Effects of the fishery on the ecosystem

Measures to reduce effects of the fishery on the ecosystem include area closures and moving rules to protect sponges and cold-water corals and to reduce bycatch, and gear modifications to reduce damage to benthic communities, and, again, to reduce bycatch.

Special comments

The number of large pre-recruits (14 - 16.5 mm, expected to recruit to next year's fishable biomass) is close to its ten-year maximum, so prospects for short-term recruitment are good; this is true both in Disko bay and offshore as well. The number at age 2 in 2015 is well above its 20-year upper quartile.

In the recent past, TAC reductions have been implemented in steps of limited size. Increases should follow a similar method.

Source of Information SCS Doc 13/04, FC Docs 04/18, SCR Docs 15/42, 43, 44, 48, 49.

Recommendation

In 2015 the stock remains at a low level, comparable to previous years, and catches should not exceed 2 000 t.

258

Management objectives

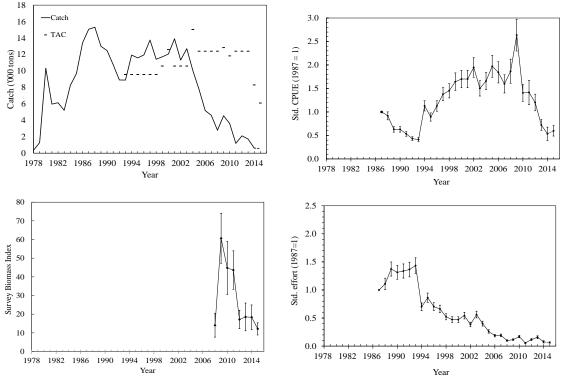

Scientific Council is aware of general management objectives specified in the Greenland Fisheries Act; however the contents of these have not been conveyed to the Council.

Advice is based on qualitative evaluation of biomass indices in relation to historic levels.

Management unit

The shrimp stock is distributed off East Greenland in ICES Div. XIVb and Va and is assessed as a single population

Stock status

The stock size remained at a very low level in 2015 despite several years of very low exploitation rates.

Reference points

No reference points have been established for this stock

Projections

Quantitative assessment of risk at various catch options is not possible for this stock at this time.

Assessment

No analytical assessment is available. Evaluation of stock status is based upon interpretation of commercial fishery and research survey data.

Human impact

Mainly fishery related mortality has been documented. Other sources (e.g. pollution, shipping, oil-industry) are considered minor.

Biological and Environmental Interactions

Cod is an important predator on shrimp. The cod stock has been increasing in East Greenland waters in recent years.

Fishery

Shrimp is caught in a directed trawl fishery. The fishery is regulated by TAC and bycatch reduction measures include move-on rules and Nordmøre grates.

Recent catches were as follows:

	2008	2009	2010	2011	2012	2013	2014	2015
Enacted TAC	12400	12835	11835	12400	12400	12400	8300	6100
SC Recommended TAC	12400	12400	12400	12400	12400	12400	2000	2000
NIPAG	2794	4555	3602	1199	2109	1717	622	572 ¹

¹ To June 2015

Effects of the fishery on the ecosystem

Measures to reduce effects of the fishery on the ecosystem include move-on rules to protect sponges and cold-water corals.

Source of Information

SCR Doc. 15/045, 15/051

V. OTHER MATTERS

1. Scheduling of Future Meetings

The schedule of future meetings

a) Scientific Council Meetings

i) Scientific Council, 21 – 25 Sep 2015

Scientific Council noted the Scientific Council meeting will be held at the Westin Hotel in Halifax, Nova Scotia, 21-25 September 2015.

ii) Scientific Council, June 2016

Scientific Council agreed that its June meeting will be held on 3 – 16 June 2016, at St Mary's University, Halifax.

iii) Scientific Council (in conjunction with NIPAG), Sep 2016

This meeting will be held at the ICES Headquarters, Copenhagen, around 7 – 14 September 2016.

iv) Scientific Council, Sep 2016

Scientific Council noted that the Annual meeting will be held in Cuba, during 19 – 23 September, 2016.

v) Scientific Council, June 2017

The Scientific Council June meeting is scheduled for 2 - 15 June 2017.

b) NAFO/ICES Joint Working Groups

i) NIPAG, 7 – 14 Sep 2016

This meeting will be held at the ICES Headquarters, Copenhagen, 7 – 14 September 2016.

ii) WG-DEC, 15 – 19 February 2016

The next meeting of the ICES – NAFO Working Group on Deepwater Ecosystems is scheduled to take place at ICES Headquarters, during 15 – 19 February 2016.

iii) WG-HARP, August 2016

WG-HARP will continue its work by correspondence. The next meeting of the ICES – NAFO Working Group on Harp and Hooded Seals is scheduled to take place in during August 2017.

c) NAFO Working Groups

iv) WG-ESA, 17-26 Nov, 2015

The Working Group on Ecosystem Science and Assessment will meet at the NAFO Secretariat, Dartmouth, Nova Scotia, Canada, 17 - 26 November, 2015.

32. Topics for Future Special Sessions

No special sessions were proposed. Scientific Council noted the thoughts of the group that a special session on growth and aging of prawns may be beneficial at a future time, however some work needs to be carried out beforehand.

33. Other Business

a) A tribute to Dave Orr

Dave Orr (September 11th, 1958 – July 5th, 2015) was a valued member of NIPAG and Scientific Council meetings over many years, acting as the designated expert for the Northern shrimp stock in Div. 3LNO, as well as working on domestic Canadian shrimp assessments. Dave passed away peacefully on Sunday July 5th, 2015 in the presence of his wife and daughters. The SC chair spoke of Dave's many qualities – the dedication he had to his work and colleagues, his friendliness, his openness and the positivity he displayed. Dave's friends at the NIPAG group held a moments silence at the opening of the meeting, and raised a glass to his memory at the reception.

b) Election of new chairs

Noting that the current chairs of NIPAG, Peter Shelton and Brian Healey (Canada) have reached the end of their current terms, the SC Chair thanked them for their service and wished them well in their next endeavours. The meeting was informed that Joel Vigneau (EU-France) had been elected as the next STACFIS chair at the June SC meeting, and he would be filling the role of NIPAG co-chair. Guldborg Soevik was elected as the other co-chair. The chair wished them all success in their new positions.

VI. ADOPTION OF SCIENTIFIC COUNCIL AND NIPAG REPORTS

The Council at its session on 16 September 2015 considered and adopted Sections III.1-4 of the "Report of the NAFO/ICES *Pandalus* Assessment Group" (SCS Doc. 15/13, ICES CM 2015/ACOM:14). The Council then considered and adopted its own report of the 9-16 September 2015 meeting.

VII. ADJOURNMENT

The Chair thanked the participants for their hard work and contribution to the success of this meeting, and welcomed the peer review and constructive comments received in formulating the scientific advice. The Chair thanked the Scientific Council Coordinator, Neil Campbell, and Dayna Bell, Scientific Information Administrator for their support during the meeting. The Chair then offered thanks to the ICES and NAFO Secretariats for their support in general, and to Department of Fisheries and Oceans for hosting the meeting and for supporting a social gathering. The report was adopted at the close of the meeting, subject to a two week period for editorial changes. All participants were then wished a safe journey home and the meeting was adjourned at 1800 hours.

Co-Chairs: Brian Healey, Peter Shelton.

Rapporteurs: Various

I. OPENING

The NAFO/ICES *Pandalus* Assessment Group (NIPAG) met at the Northwest Atlantic Fisheries Centre, St. John's, Newfoundland during 9-16 September 2015 to review stock assessments referred to it by the Scientific Council of NAFO and by the ICES Advisory Committee. Representatives attended from Canada, Denmark (in respect of Faroe Islands and Greenland), European Union (Denmark, Estonia, Spain and Sweden), Iceland, Norway, and the United States of America. The NAFO Scientific Council Coordinator and Scientific Information Officer were also in attendance.

II. GENERAL REVIEW

1. Review of Research Recommendations in 2014

These are given under each stock in the "stock assessments" section of this report.

34. Review of Catches

Catches and catch histories were reviewed on a stock-by-stock basis in connection with each stock.

STOCK ASSESSMENTS

1. Northern Shrimp on Flemish Cap (NAFO Div. 3M)

(SCR Doc. 15/047)

Environmental Overview

Recent Conditions in Ocean Climate and Lower Trophic Levels

• Ocean climate composite index for the Flemish Cap has trended downward since 2010 to a negative level in 2014 after 16 years of consecutive above average conditions.

• The composite spring bloom index in 3LM has shifted to negative levels in 2013-2014 after relatively high positive anomalies observed in previous 5 years.

• The composite zooplankton index has remained above normal since 2009 and reached its highest level in 2014.

• The composite trophic index increased to its highest level in 2014.

a) Introduction

The shrimp fishery in Div. 3M is now under moratorium. This fishery began in 1993. Initial catch rates were favorable and, shortly thereafter, vessels from several nations joined. Catches peaked at over 60 000 t in 2003 and declined thereafter.

Fishery and catches: A moratorium was imposed in 2011. Catches are expected to be close to zero in 2015. Recent catches were as follows:

	2006	2007	2008	2009	2010	2011	2012	2013	2014	2015
NIPAG	18000	21000	13000	5000	2000	0	0	0	0	01
STATLANT 21	15191	17642	13431	5374	1976	0	0	0	0	
SC	48000	48000	17000-	18000-	ndf	ndf	ndf	ndf	ndf	ndf
Recommended			32000	27000						
Catches										
Effort ² (Agreed	10555	10555	10555	10555	5227	0	0	0	0	0
Days)										

¹ To September 2015

² Effort regulated

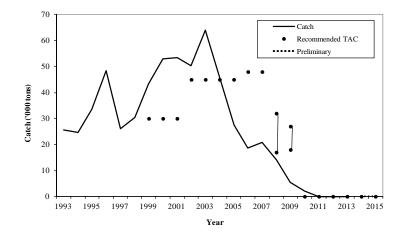

Fig. 1.1. Shrimp in Div. 3M: Catches (t) of shrimp on Flemish Cap and TACs recommended in the period 1993-2015. Due to a moratorium, the shrimp catch is expected to be zero in 2015.

b) Input Data

i) Commercial fishery data

Time series of size and sex composition data were available mainly from Iceland and Faroes between 1993 and 2005. Because of the moratorium catch and effort data have not been available since 2010, and therefore the standardized CPUE series has not been extended.

ii) Research Survey Data

Stratified-random trawl surveys have been conducted on Flemish Cap by the EU in July from 1988 to 2015. A new vessel was introduced in 2003 which continued to use the same trawl employed since 1988. In addition, there were differences in cod-end mesh sizes utilized in the 1994 and 1998 surveys that have likely resulted in biased estimates of total survey biomass. Nevertheless, for this assessment, the series prior to 2003 were converted into comparable units with the new vessel using the methods accepted by STACFIS in 2004 (NAFO 2004 SC Rep., SCR Doc. 04/77).

c) Assessment Results

No analytical assessment is available. Evaluation of stock status is based upon interpretation of commercial fishery up to 2010, and research survey data.

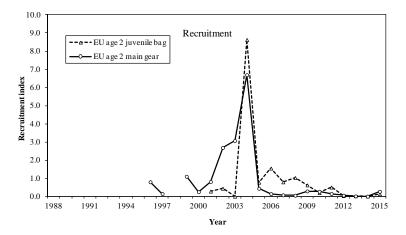

Fig. 1.2. Shrimp in Div. 3M: Abundance indices at age 2 from the EU survey. Each series was standardized to its mean.

Recruitment: All year-classes after the 2002 cohort (i.e. age 2 in 2004) have been weak

SSB: The survey female biomass index was stable at a high level from 1998 to 2007, and has declined since then. In 2015 although the female biomass increased (48%) over 2014, the estimated biomass (1057 t.) remained among the lowest recorded in the historical series, well below B_{lim} .

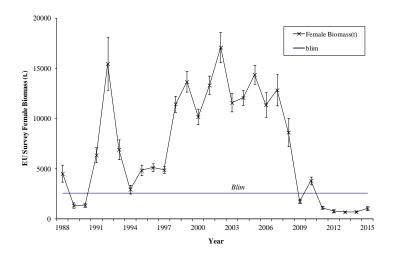

Fig. 1.3. Shrimp in Div. 3M: Female biomass index from EU trawl surveys, 1988-2015. Error bars are 1 std. err.

Exploitation rate: Because of low catches, followed by the moratorium, the exploitation rate index (nominal catch divided by the EU survey biomass index of the same year) has declined to near zero.

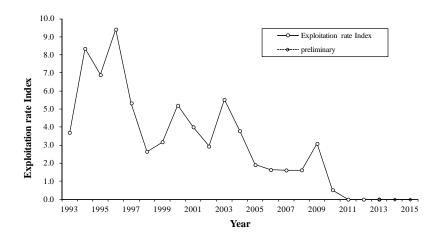

Fig. 1.4. Shrimp in Div. 3M: exploitation rate index as derived by catch divided by the EU survey biomass index of the same year.

d) State of the Stock

Following several years of low recruitment, the spawning stock has declined, and has remained below B_{lim} since 2011. Due to continued poor recruitment there are concerns that the stock will remain at low levels.

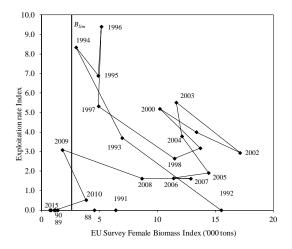

Fig. 1.5. Shrimp in Div. 3M: Exploitation rate index plotted against female biomass index from EU survey. Line denoting B_{lim} is drawn where biomass is 15% of the maximum point in 2002. Due to the moratorium on shrimp fishing the expected catch in 2015 is 0 t.

e) **Reference Points**

Scientific Council considers that a female survey biomass index of 15% of its maximum observed level provides a proxy for B_{lim} . This corresponds to an index value of 2 564. The index has been below B_{lim} since 2010. A limit reference point for fishing mortality has not been defined.

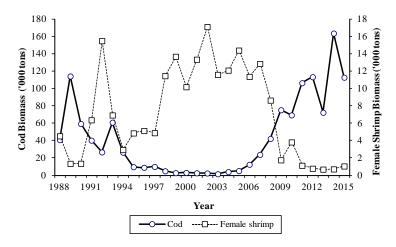

f) Ecosystem considerations

The drastic decline of shrimp biomass since 2007 correlates with the increase of the cod stock in Div. 3M. It is uncertain whether this represents a causal relationship and/or covariance as the result of an environmental factor.

The environment, trophic interactions, and fisheries are important drivers of fish stock dynamics. Analyses of fish stomachs over 1990 to 2012 show an increasing proportion of shrimp in the diets of most fish species.

Since the early 2000s, there has been an increase of redfish in the diet of large individuals of predatory species. These trends are observed throughout the Flemish Cap fish community.

Results of modelling suggest that, in unexploited conditions, cod would be expected to be a highly dominant component of the system, and high shrimp stock sizes, like the ones observed in the 1998 – 2007 period, would not be a stable feature in the Flemish Cap.

g) Research Recommendations

For Northern Shrimp in Div. 3M NIPAG **recommends** that further exploration of the relationship between shrimp, cod and the environment be continued in WGESA and NIPAG encourages the shrimp experts to be involved in this work.

No progress.

35. Northern Shrimp (Pandalus borealis) in NAFO Div. 3LNO

(SCR Doc. 14/048, 15/048, /055)

Environmental Overview

Recent Conditions in Ocean Climate and Lower Trophic Levels

• Ocean climate composite index on the Grand Bank transitioned to a weak negative value in 2014 after 16 consecutive years of above normal conditions, similar to the pattern observed on the Flemish Cap.

• The composite spring bloom index has returned to near normal in 2014 after negative anomalies observed in 2012-2013.

• The composite zooplankton index has remained above normal since 2009.

• The composite trophic index has remained near normal in recent years.

a) Introduction

This shrimp stock is distributed around the edge of the Grand Bank, mainly in Div. 3L. The fishery began in 1993 and came under TAC control in 2000 with a 6 000 t TAC and fishing restricted to Div. 3L. Annual TACs were raised several times between 2000 and 2009 reaching a level of 30 000 t for 2009 and 2010. The TAC was then reduced annually until no directed fishing was implemented for 2015 (Fig. 2.1). The TAC entries in the table have been updated with corrected autonomous TACs from Denmark and the STATLANT 21 entries updated from the NAFO website.

	2006	2007	2008	2009	2010	2011	2012	2013	2014	2015

NIPAG ²	25689	23570	25407	25900	20536	12900	10108	8647	2289	

Recent catches and TACs (t) for shrimp in Div. 3LNO (total) are as follows:

¹ Includes autonomous TAC as set by Denmark.

² NIPAG catch estimates have been updated using various data sources (see p. 13, SCR. 14/048).

Since this stock came under TAC regulation, Canada has been allocated 83% of the TAC. This allocation is split between a small-vessel (less than 500 GT and less than 65 ft) and a large-vessel fleet. The annual quota within the NAFO Regulatory Area (NRA) is 17% of the total TAC. Denmark (Faroes and Greenland) did not agree to the quotas during the years 2003-2014 and set their own TACs at about 10% of the total NAFO recommended TAC rather than the 1% recommended for them by NAFO.

The use of a sorting grid to reduce bycatch of fish is mandatory for all fleets in the fishery. The sorting grid cannot have a bar spacing greater than 22 mm.

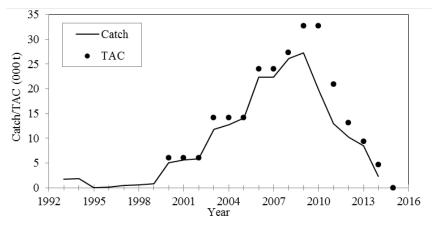

Fig. 2.1. Shrimp in Div. 3LNO: Catches and TAC. The TAC illustrated includes the autonomous quotas, set by Denmark, with respect to Faroes and Greenland.

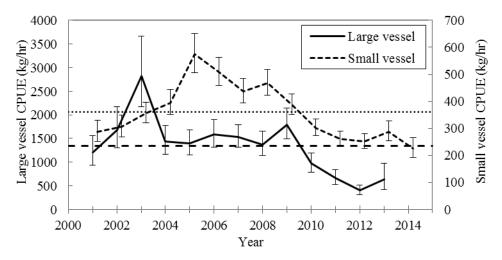

b) Input Data

i) Commercial fishery data

Effort and CPUE.

Catch and effort data have been available from vessel logbooks and observer records since 2000, however there was no fishery in 2015 and observer records utilized for large vessel CPUE are not yet available for 2014. The 2010 - 2014 indices for small vessel CPUEs were significantly lower than the long term mean and were similar to the 2001 values while the large vessel CPUEs were the lowest in the time series (Fig. 2.2). CPUE, while reflecting fishery performance, is not effectively indicating the status of the resource. The trends of these CPUE indices show conflicting patterns with the survey biomass indices and were therefore not used as indicators of stock biomass.

271

Logbook data from Spain and Estonia, were available for the shrimp fishery within the NRA in 2014. The data was insufficient to produce a standardized CPUE model.

Catch composition. Length compositions were derived from Canadian (2003 – 2012) and Estonian (2010 – 2014) observer datasets. Catches appeared to be represented by a broad range of size groups of both males and females.

ii) Research survey data

Canadian multi-species trawl survey. Canada has conducted stratified-random surveys in Div. 3LNO, using a Campelen 1800 shrimp trawl, from which shrimp data is available for spring (1999–2015) and autumn (1996–2014). The autumn survey in 2004 and the spring survey in 2015, were incomplete and therefore of limited use for the assessment. The autumn 2014 survey only surveyed Div. 3L, however since about 95% of the biomass in Div. 3LNO comes from 3L, it was considered useful as a proxy for Div. 3LNO in 2014.

Results from a revised version of Ogmap were presented in comparison to the version utilized in previous years. The meeting decided to continue with the previous version for use and incorporation into this report. Work will continue on the new version for future assessments. **Spanish multi-species trawl survey**. EU-Spain has been conducting a stratified-random survey in the NRA part of Div. 3L since 2003. Data is collected with a Campelen 1800 trawl. There was no Spanish survey in 2005.

Biomass. In Canadian surveys, over 90% of the biomass was found in Div. 3L, distributed mainly along the northeast slope in depths from 185 to 550 m. Since Div. 3NO was not sampled during autumn 2014, the biomass index displayed for that season and year is based solely on Div. 3L. There was an overall increase in both the spring and autumn indices to 2007 after which they decreased by over 90% to 2013. The spring

2014 survey index increased compared to 2013, however the autumn index decreased further (Fig. 2.3). Confidence intervals from the spring surveys are usually broader than from the autumn surveys.

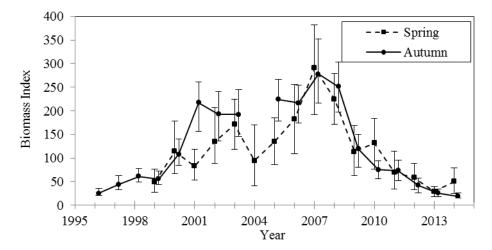

Fig. 2.3. Shrimp in Div. 3LNO: Total biomass index estimates from Canadian spring and autumn multi-species surveys (with 95% confidence intervals). The 2014 autumn index is for Div. 3L only.

Spanish survey biomass indices for Div. 3LNO, within the NRA only, increased from 2003 to 2008 followed by a 93% decrease by 2012 remaining near that level through 2015 (Fig. 2.4).

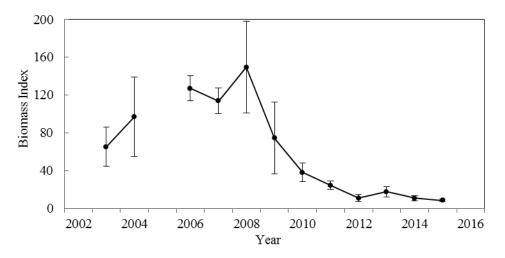

Fig. 2.4. Shrimp in Div. 3LNO: Biomass index estimates from EU - Spanish multi-species surveys (± 1 s.e.) in the NRA of Div. 3LNO.

Female Biomass (SSB) indices. The spring Div. 3LNO female SSB index decreased by 91% between 2007 and 2013, however it increased slightly in 2014. The autumn SSB index showed an increasing trend to 2007 but decreased 92% by 2014 (Fig. 2.5).

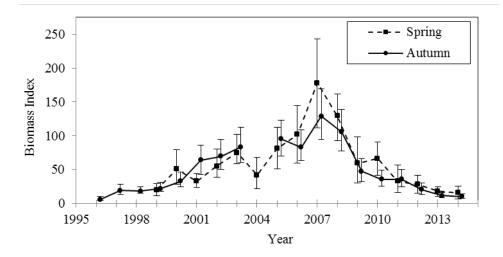

Fig. 2.5. Shrimp in Div. 3LNO: Female SSB indices from Canadian spring and autumn multispecies surveys (with 95% confidence intervals). The autumn index for 2014 is for Div. 3L only.

Stock Composition.

Both males and females showed a broad distribution of lengths in recent surveys indicating the presence of more than one year class (Fig. 2.6).

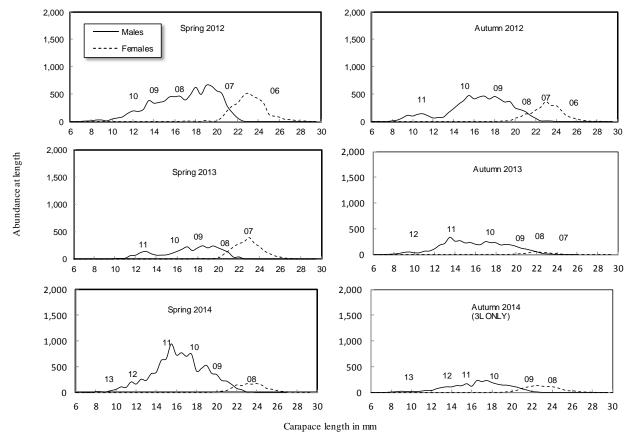

Fig. 2.6. Shrimp in Div. 3LNO: Abundance at length estimates, from Canadian multi-species survey data, as calculated using Ogmap. The numbers within each plot indicate likely year classes.

Recruitment indices. The recruitment indices were based upon abundance indices of all shrimp with carapace lengths of 11.5 – 17 mm from Canadian multi-species survey data. These animals are thought to be one year away from the fishery. The 2006 – 2008 recruitment indices were among the highest in both spring and autumn time series. Both indices decreased through to autumn 2013. The spring index increased in 2014, with a high degree of uncertainty (Fig. 2.7). The increase in the spring 2014 index was highly influenced by a couple large catches of small male shrimp, however there were no evidence that they contributed to the biomass in autumn 2014 and recruitment still appears to be low.

274

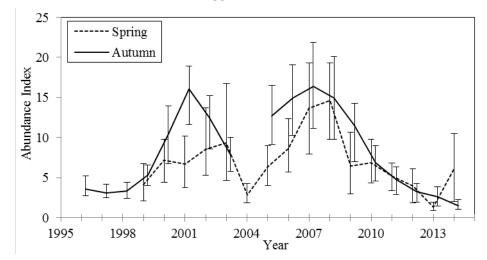

Fig. 2.7. Shrimp in Div. 3LNO: Recruitment indices derived from abundances of all shrimp with 11.5 – 17 mm carapace lengths from Canadian spring and autumn bottom trawl survey (1996–2014) data. Error bars represent 95% confidence intervals. The autumn index for 2014 is for Div. 3L only.

Fishable biomass and exploitation index. The spring fishable biomass (shrimp > 17mm CL) index increased to 2007 but has since decreased by 89% through to 2013 followed by a slight increase during 2014. Similarly, the autumn fishable biomass showed an increasing trend until 2007 then decreased by 93% through to 2014 (Fig. 2.8).

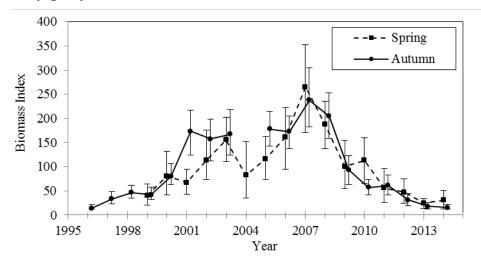

Fig. 2.8. Shrimp in Div. 3LNO: fishable (shrimp >17mm CL) biomass index. Bars indicate 95% confidence limits. The autumn index for 2014 is for Div. 3L only.

An index of exploitation was derived by dividing the catch in a given year by the fishable biomass index from the previous autumn survey. The exploitation index generally increased throughout the course of the fishery

until dropping sharply in 2014. (Fig. 2.9). The exploitation rate for 2015 is not illustrated but is expected to be 0.

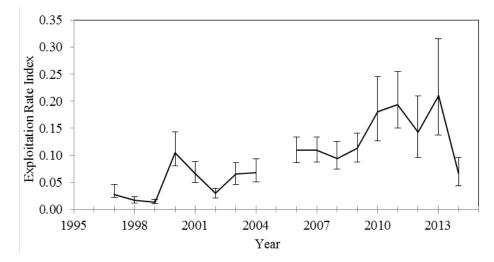

Fig. 2.9. Shrimp in Div. 3LNO: exploitation rates calculated as a year's catch divided by the previous year's autumn fishable biomass index. Bars indicate 95% confidence limits.

c) Assessment Results

Recruitment. Recruitment indices have decreased since 2008 and are now among the lowest observed values.

Biomass. Spring and autumn biomass indices have decreased considerably since 2007 and are now among the lowest observed values.

Exploitation. The index of exploitation generally increased over the 1997 – 2013 period but declined sharply in 2014 and is expected to be zero in 2015.

State of the Stock. The stock has declined since 2007, and in 2014 the risk of being below *B*_{*lim*} is greater than 95%.

Given expectations of poor recruitment, the stock is not predicted to increase in the near future.

d) Reference Points

The point at which a valid index of stock size has declined to 15% of its highest observed value is considered to be B_{lim} (SCS Doc. 04/12). The 2014 autumn female biomass index, for Div. 3L, was 10 000 t, and in 2014 the risk of being below B_{lim} was greater than 95% (Fig 2.10). A limit reference point for fishing mortality has not been defined.

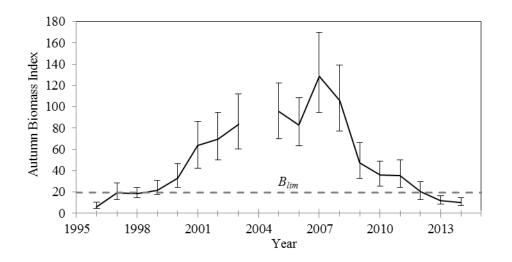

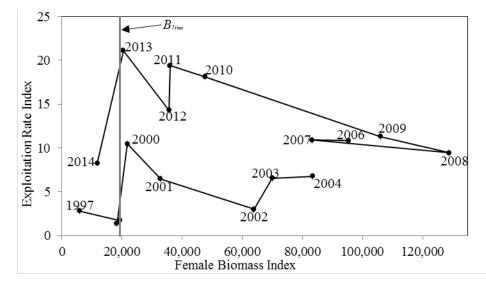

Fig. 2.10. Shrimp in Div. 3LNO: autumn female spawning stock biomass (SSB) and precautionary approach *B_{lim}*. *B_{lim}* is defined as 15% of the maximum autumn female biomass over the time series. Bars indicate 95% confidence limits. The autumn index for 2014 is for Div. 3L only.

e) Research Recommendations

It is **recommended** that ecosystem information related to the role of shrimp as prey in the Grand Bank (i.e. 3LNO) Ecosystem be presented to the 2016 NIPAG meeting.

36. Northern shrimp (NAFO Subareas 0 and 1)

(SCR Docs 04/75, 04/76, 08/6, 11/53, 11/58, 12/44, 13/54, 15/042, 15/043, 15/044, 15/048, 15/049; SCS Doc. 04/12)

Environmental Overview

Recent Conditions in Ocean Climate and Lower Trophic Levels

• The composite climate index in Subarea 1 has remained above or near normal in recent years but has trended downward from the record-high in 2010.

• The composite spring bloom index remains well below normal since 2012.

a) Introduction

The shrimp stock off West Greenland is distributed mainly in NAFO Subarea 1 (Greenland EEZ), but a small part of the habitat, and of the stock, intrudes into the eastern edge of Div. 0A (Canadian EEZ). Canada has defined 'Shrimp Fishing Area 1' (Canadian SFA1), to be the part of Div. 0A lying east of 60°30'W, i.e. east of the deepest water in this part of Davis Strait.

The stock is assessed as a single population. The Greenland fishery exploits the stock in Subarea 1 (Div. 1A–1F). Since 1981 the Canadian fishery has been limited to Div. 0A.

Three fleets, one from Canada and two from Greenland (offshore and coastal) have participated in the fishery since the late 1970s. The Canadian fleet and the Greenland offshore fleet have been restricted by areas and quotas since 1977. The Greenland coastal fleet has privileged access to inshore areas (primarily Disko Bay and Vaigat in the north, and Julianehåb Bay in the south). Coastal licences were originally given only to vessels under 80 tons, but in recent years larger vessels have entered the coastal fishery. Greenland allocates a quota to EU vessels in Subarea 1; this quota is usually fished by a single vessel which, for analyses, is treated as part of the Greenland offshore fleet. Mesh size is at least 44 mm in Greenland, 40 mm in Canada. Sorting grids to reduce bycatch of fish are required in both of the Greenland fleets and in the Canadian fleet. Discarding of shrimps is prohibited.

The TAC advised for the entire stock for 2004–2007 was 130 000 t, reduced for 2008–2010 to 110 000 t and increased again for 2011 to 120 000 t. The TAC advised for 2012 was 90 000t. For 2012, Greenland enacted a TAC of 101 675 t for Subarea 1; Canada enacted a TAC of 16 921 t for SFA 1. Further deterioration of the assessed status of the stock in 2012 induced yet lower advised TACs of 80 000 t for 2013 and 2014 and 60 000 t for 2015. In 2015 Greenland enacted a TAC of 71 061 t with quotas of 2 000, 39 365 and 29 696 t, and Canada a TAC of 8 500 t.

Greenland requires that logbooks should record catch live weight. For shrimps sold to on-shore processing plants, a former allowance for crushed and broken shrimps in reckoning quota draw-downs was abolished in 2011 to bring the total catch live weight into closer agreement with the enacted TAC. However, in previous years, the coastal fleet catching bulk shrimps did not log catch weights of *P. montagui* separately from *borealis;* weights were estimated by catch sampling at the point of sale and the price adjusted accordingly, but the weight of *montagui* was not deducted from the quota (SCR Doc. 11/53). Logbook-recorded catches could therefore still legally exceed quotas. Since 2012 *P. montagui* has been included among the species protected by a 'moving rule' to limit bycatch and there are no licences issued for directed fishing on it (SCR Doc. 15/42). Instructions for reporting *montagui* in logbooks were changed in 2012, to improve the reporting of these catches.

The table of recent catches was updated (SCR Doc. 15/48). Total catch increased from about 10 000 t in the early 1970s to more than 105 000 t in 1992 (Fig. 3.1). Moves by the Greenlandic authorities to reduce effort, as well as fishing opportunities elsewhere for the Canadian fleet, caused catches to decrease to about 80 000 t by 1998. Total catches increased to average over 150 000 t in 2005–08, but have since decreased, to 88 765 t in 2014 and 65 000 t (projected) in 2015.

Recent catches, projected catches for 2015 and recommended and enacted TACs (t) for Northern Shrimp in Div. 0A south of 73°30N and east of 60°30'W and in Subarea 1 are as follows:

1 Total catches for the year as predicted by inductry observers										

¹ Total catches for the year as predicted by industry observers.

² Provisional

³ Canada and Greenland set independent autonomous TACs.

Until 1988 the fishing grounds in Div. 1B were the most important. The offshore fishery subsequently expanded southward, and after 1990 catches in Div. 1C–D, taken together, began to exceed those in Div. 1B. However, since about 1996 catch and effort in southern West Greenland have continually decreased, and since 2008 effort in Div. 1F has been virtually nil (SCR Doc. 15/42).

In 2002–2005 the Canadian catch in SFA1 was stable at 6000 to 7000 t - about 4–5% of the total - but since 2007 fishing effort has been sporadic and catches variable, averaging about 1750 t in 2007–11 and since 2012 no fishing has been conducted in SFA1 (SCR Doc. 15/48).

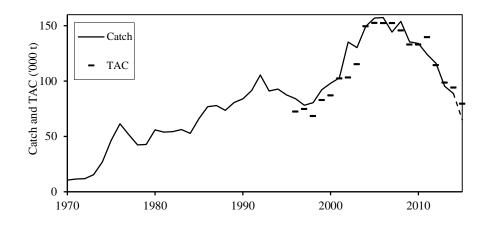

Fig. 3.1 Northern shrimp in Subarea 1 and Canadian SFA1: enacted TACs and total catches (2015 predicted for the year).

b) Input Data

i) Fishery data

Fishing effort and CPUE. Catch and effort data from the fishery were available from logbooks from Canadian vessels fishing in Canadian SFA 1 and from Greenland logbooks for Subarea 1 (SCR Doc. 15/42). In recent

years both the distribution of the Greenland fishery and fishing power have changed significantly: for example, larger vessels have been allowed in coastal areas; the coastal fleet has fished outside Disko Bay; the offshore fleet now commonly uses double trawls; and the previously rigid division between the offshore and coastal quotas has been relaxed and quota transfers between the two fleets are now allowed. A change in legislation effective since 2004 requiring logbooks to record catch live weight in place of a previous practice of under-reporting would, by increasing the recorded catch weights, have increased apparent CPUEs since 2004; this discontinuity in the CPUE data was corrected in 2008.

CPUEs were standardised by linearised multiplicative models including terms for vessel, month, year, and statistical area; the fitted year effects were considered to be series of annual indices of total stock biomass. Series for the Greenland fishery after the end of the 1980s were divided into 2 fleets, a coastal and an offshore; for those ships of the present offshore fleet that use double trawls, only double-trawl data was used. In 2013 for the first time catch and effort data for statistical area 0, which extends north to 73°30N, comprises about 82 000 sq. km. and in 2007–14 yielded 17% of the offshore catch, was included in the CPUE analyses. A series for 1976–1990 was constructed for the KGH (Kongelige Grønlandske Handel) fleet of sister trawlers and a series for 1989–96, 1998–2007 and 2010–11 for the Canadian fleet fishing in SFA1 (Fig. 3.2). The standardised CPUE estimate for the Canadian fleet in 2011 was anomalously low; close examination of the data confirmed that there had been low catch rates and little fishing. This value has little influence on the unified series.

The four CPUE series were unified in a separate step to produce a single series that was input to the assessment model. This all-fleet standardised CPUE was variable, but on average moderately high, from 1976 through 1987, but then fell to lower levels until about 1997, after which it increased markedly to peak in 2008 at over twice its 1997 value (Fig. 3.2). Values for 2009 to 2015 have been lower but remain relatively high (SCR Doc. 15/42).

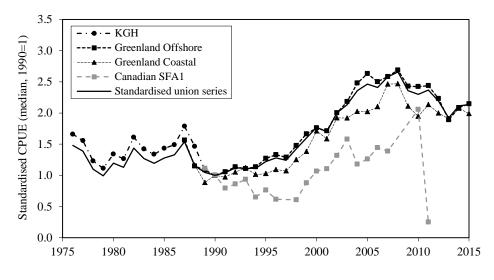

Fig. 3.2 Northern shrimp in Subarea 1 and Canadian SFA1: standardised CPUE index series 1976–2015.

The distribution of catch and effort among statistical areas was summarised using Simpson's diversity index to calculate an 'effective' number of statistical areas being fished as an index of how widely the fishery is distributed (Fig 3.3). The fishery area has contracted; NIPAG has for some years been concerned for effects of this contraction on the relationship between CPUE and stock biomass, and in particular that relative to earlier years biomass might be overestimated by recent CPUE values.

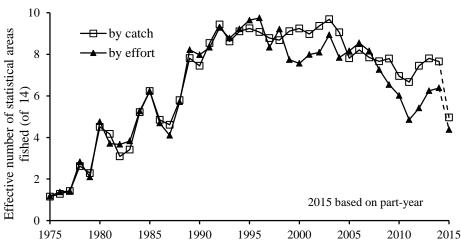

Fig. 3.3 Northern shrimp in Subarea 1 and Canadian SFA1: indices for the distribution of the Greenland fishery between statistical areas in 1975–2015.

From the end of the 1980s there was a significant expansion of the fishery southwards and in 1996–98 areas south of Holsteinsborg Deep (66°00'N) accounted for 65% of the Greenland catch. The effective number of statistical areas being fished in SA 1 reached a plateau in 1992–2003. The range of the fishery has since contracted northwards and the effective number of statistical areas being fished has decreased.

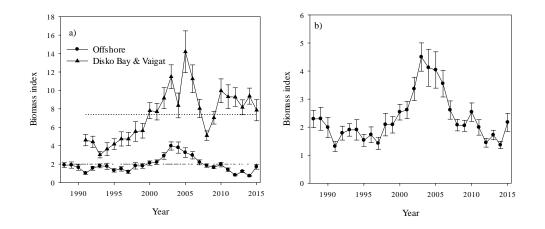

Catch composition. There is no biological sampling programme from the fishery that is adequate to provide catch composition data to the assessment.

ii) Research survey data

Greenland trawl survey. Stratified semi-systematic trawl surveys designed primarily to estimate shrimp stock biomass have been conducted since 1988 in offshore areas and since 1991 also inshore in Subarea 1 (SCR Doc. 15/43). From 1993, the survey was extended southwards into Div. 1E and 1F. A cod-end liner of 22 mm stretched mesh has been used since 1993. From its inception until 1998 the survey only used 60-min. tows, but since 2005 all tows have lasted 15 min. In 2005 the *Skjervøy 3000* survey trawl used since 1988 was replaced by a *Cosmos 2000* with rock-hopper ground gear, calibration trials were conducted, and the earlier data was adjusted.

The survey average bottom temperature increased from about 1.7°C in 1990–93 to about 3.1°C in 1997–2015 (SCR Doc. 15/43). About 80% of the survey biomass estimate is in water 200–400 m deep. In the early 1990s, about ³/₄ of this 80% was deeper than 300 m, but after about 1995 this proportion decreased and since about 2001 has been about ¹/₄, and most of the biomass has been in water 200–300 m deep (SCR Doc. 15/43). The proportion of survey biomass in Div. 1E–F has been low in recent years and the distribution of survey biomass, like that of the fishery, has become more northerly.

Biomass. The survey index of total biomass remained fairly stable from 1988 to 1997 (c.v. 18%, downward trend 4%/yr). It then increased by, on average, 19%/yr until 2003, when it reached 316% of the 1997 value. Subsequent values were consecutively lower, by 2008–2009 less than half the 2003 maximum (Fig. 3.4); this decline continued in the subsequent years, reaching in 2014 the second lowest level in the last 20 years (SCR Doc. 15/43). In 2015 survey biomass overall increased by 60% over 2015, while offshore survey biomass was 137% higher in 2015 than in 2014, about 85% of its previous maximum in 2010, in Disko Bay and Vaigat the survey biomass is 16% less than in 2014 (Fig. 3.4). Offshore regions comprise 73% of the total biomass, and 27% is inshore in Disko Bay and Vaigat. Although, the inshore regions, had far higher densities than other areas, almost three times as high as offshore (Fig. 3.4) (SCR Doc. 15/43).

Length and sex composition (SCR 15/043).

In 2012 overall the fishable biomass at 91.1% of total was a little below its 20-year median, but included an exceptionally high proportion of females. Pre-recruits (14 - 16.5mm), expected to recruit to next year's fishable biomass) have been few since 2008 in absolute numbers. In 2013 the fishable biomass was estimated to have increased by one-third, but this seemed entirely due to increases in number and biomass of females, which composed an exceptionally high proportion of the stock (SCR Doc. 14/52). This size distribution continued in 2014 were females composed a high proportion of both the fishable and total biomass, while both fishable males and unrecruited males at 14–16.5 mm remain low in absolute numbers and as a proportion of the stock.

In 2015, in both regions males compose a higher proportion close to their 10-year median of the survey biomass, of both the total and fishable biomass indices, but females comprised a record low proportion of the offshore index, well below the lower quartile. In contrast, the index in 2014 in both inshore and offshore areas were 'all females'.

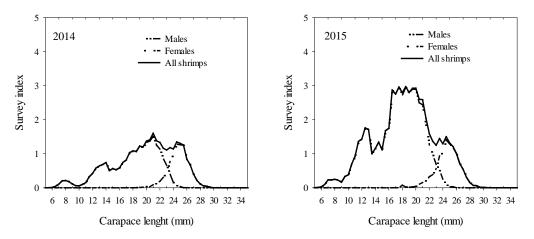

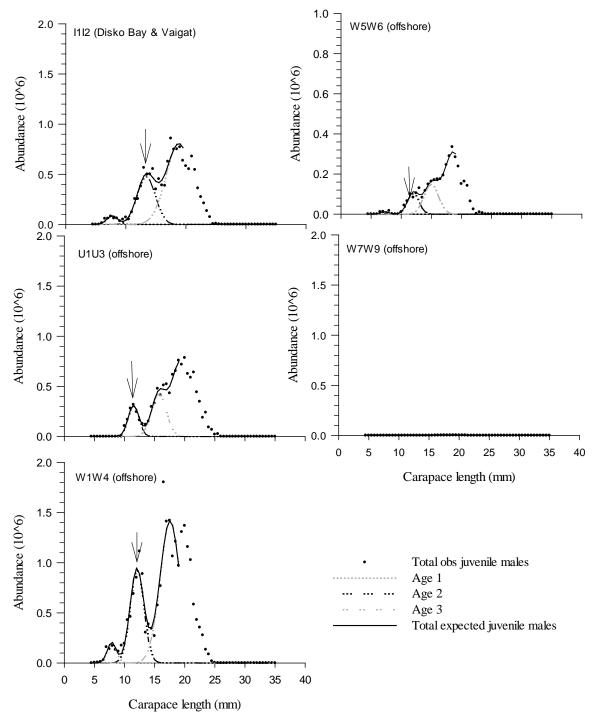

Fig. 3.5 Northern Shrimp in Subarea 1 and Canadian SFA 1: survey mean catch rates at length in the West Greenland trawl survey in 2014 and 2015.

282

Recruitment Index. In 2015 numbers at age 2 were estimated by fitting Normally distributed components to the length distribution, but only as far as 19 mm CPL. In other words, two components, considered age-1 and age-2, were fully fitted, and a third component was fitted only on its left-hand limb (SCR Doc. 15/43). Components were required to have equal CVs of CPL. This method was used to revise numbers at age 2 back to 2005.

From 2014 to 2015, numbers at age 2 increased by more than four times offshore, but remain at a comparable 2014 level in Disko bay & Vaigat. In total number of age 2 is well above its 20-year upper quartile (SCR Doc, 15/43) (Fig. 3.7). The stock composition inshore has historically been characterized by higher proportion of young shrimps than that offshore.

283

The relative number of large pre-recruits (14 – 16.5mm, expected to recruit to next year's fishable biomass) is close to its ten-year maximum, so prospects for short-term recruitment are good; this is true both in Disko bay & Vaigat and offshore as well.

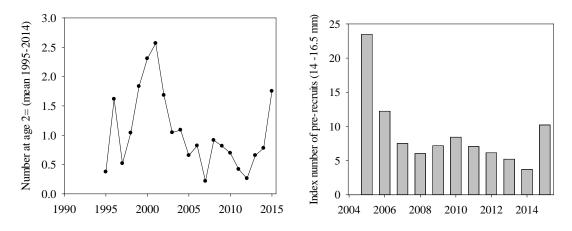

Fig. 3.7 Northern Shrimp in Subarea 1 and Canadian SFA 1: survey index of numbers at age 2, 1995–2015 and index of number of pre-recruits (4-16.5mm), 2005-2015.

c) Assessment Results

i) Estimation of Parameters

A Schaefer surplus-production model of population dynamics was fitted to series of CPUE, catch, and survey biomass indices (SCR Doc. 15/44).

Series of estimates of cod biomass in West Greenland waters are available for different periods from VPA, from the German groundfish survey at West Greenland and from the Greenland trawl survey for shrimps. The results from the German survey for the current year are not available in time for the assessment. Heretofore the estimate from the German survey has been used as the main estimate, the Greenland trawl survey value, adjusted, being used only for the current year.

The model includes a term for predation by Atlantic cod. In 2014 the full Greenland trawl survey was combined with the German survey within the assessment model, the two always having been well correlated, to produce an overall cod-stock biomass estimate series. The estimate for the current year depends only on the (scaled) Greenland survey value, the German survey being late in the year. The methods used in the German survey have recently been reviewed and revised; past estimates were little changed. The index of cod biomass is adjusted by a measure of the overlap between the stocks of cod and shrimps in order to arrive at an index of 'effective' cod biomass, which is used in the assessment model to estimate predation.

Total catches for 2015 were projected at 65 000 t. The assessment model had been modified in 2012 to include the uncertainty of projecting the current year's catches. The model was run with data series shortened to 30 years to speed up the running; the effect of shortening the data series was checked and found not significant (SCR Doc. 11/58). Stability of the assessment was checked by looking at changes, due to the addition of subsequent years' data, in year-end stock status estimates. Though slight changes occurred, they were commensurate with fluctuations in biomass indices and did not trend either up or down.

Corrections to coding of the quantitative assessment model for 2015 were reviewed by NIPAG. They included wider (less informative) prior distributions for parameters of the function relating predation to biomasses of predator and prey, and revised calculation of future mortalities. Both would tend to result in calculated

mortalities lower than before under the conditions now expected in 2016, viz. high biomass of shrimps and moderately high biomass of cod.

These changes to coding appear to be responsible for about half of the improvement in apparent stock status at the end of 2015 compared with the corresponding values for the end of 2014. The other half is due to the increases in biomass observed in survey and CPUE indices for 2015. The modelled biomass (Fig. 3.8a) was low and stable until the late 1990s, when it started a rapid increase. Biomass doubled by about 2004; the survey index increased much more than the fishery CPUE. Over 2004 - 2013 modelled biomass steadily declined but has since stabilized at a level similar to that of the late 1990s, close to B_{msy} .

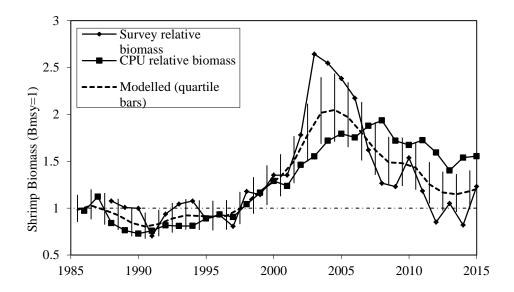

Fig. 3.8a: Northern Shrimp in SA 1 and Canadian SFA1: trajectory of the median estimate of relative stock biomass at start of year 1986–2015, with median CPUE and survey indices; 30 years' data with constrained CVs.

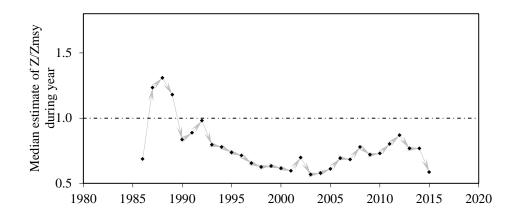

Fig 3.8b: Northern Shrimp in SA 1 and Canadian SFA1: trajectory of the median modelled estimate of mortality relative to Z_{msy} during the year, 1986–2015.

Mortality has generally been below Z_{msy} during the modelled period, although a short-lived episode of high cod biomass occasioned three years of high values in the late 1980s (Fig. 3.8b). From 1998 to 2005 total

mortality was noticeably low—in 1998–2001 because catches were still below 100 Kt while the stock had started to increase, in 2002–05 because the stock biomass increased, to high levels, much faster than catches.

Estimates of stock-dynamic and fit parameters from fitting a Schaefer stock-production model, to 30 years' data on the West Greenland stock of the Northern shrimp in 2015 is given in the table below. Median values from the 2014 assessment are provided for comparison. Biomass at the end of 2015 is projected to be above the 2014 value and is 23% above B_{msy} . The assumed catches for 2015 (65 000 t) are expected to hold total mortality below 58.6 % of Z_{msy}

	Mean	S.D.	25%	Median	75%	Est.	Median

d) State of the stock

Recruitment. The number of large pre-recruits (14 – 16.5mm, expected to recruit to next year's fishable biomass) is close to its ten-year maximum, so prospects for short-term recruitment are good; this is true both in Disko and offshore as well. The number at age 2 in 2015 is well above its 20-year upper quartile.

Biomass. A stock-dynamic model showed a maximum biomass in 2004 with a continuing decline over 2004 – 2013. The decline appears to have paused At the end of 2015, the stock is estimated to be 23% above B_{msy} . The risk of being below B_{lim} (30% of B_{msy}) is very low (<1%).

Mortality. With 2015 catches projected at 65 000 t the risk that total mortality will exceed Z_{msy} is estimated to be 58.6%. Atlantic cod is, in 2015, still concentrated in southerly areas where shrimps are now scarce, but its biomass is high and predation pressure is expected to be at least as high as the previous 3 years.

State of the Stock. Biomass is estimated to have been declining since 2004, but at the end of 2015 is projected to be above B_{msy} The risk of being below B_{lim} (30% of B_{msy}) is very low (<1%).d)

Precautionary Approach

 B_{lim} has been established as 30% B_{msy} , and Z_{msy} (fishery and cod predation) has been set as the mortality reference point.

The fitted trajectory of stock biomass showed that the stock had been below its MSY level until the late 1990s, with mortalities mostly near the MSY mortality level except for an episode of high mortality associated with a short-lived resurgence of cod in the late 1980s. In the mid-1990s, with cod stocks at low levels, biomass started to increase at low mortalities to reach high proportions of B_{msy} in 2003–05. Recent increases in the cod stock coupled with high catches have been associated with higher mortalities and continuing decline in the modelled biomass. At the end of 2015, the stock will be above B_{msy} , and the risk of being below B_{lim} (30% of B_{msy}) is very low (<1%).

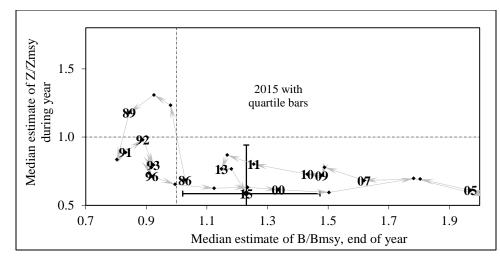

Fig. 3.9: Northern shrimp in Subarea 1 and Canadian SFA1: trajectory of relative biomass and relative mortality, 1986–2015.

e) Projections

Predicted probabilities of transgressing precautionary reference points in 2016 – 2018 under seven catch options and subject to predation by a cod stock with an effective biomass of 55 Kt (the value for 2015 being 56Kt.). Additional projections assuming an effective cod biomass of 65Kt were conducted (not shown) and results indicated small differences in risk probabilities.

55 000 t cod	Catch option ('000 tons)							
Risk of:	60	70	75	80	85	90	95	100
falling below B_{msy} end 2016 (%)	25.0	25.0	25.4	26.2	26.6	26.6	27.0	27.2
falling below B_{msy} end 2017 (%)	25.3	26.0	26.5	27.4	27.7	28.4	29.2	30.3
falling below B_{msy} end 2018 (%)	26.4	27.8	28.9	29.7	30.5	31.0	32.1	33.0
falling below <i>B</i> _{lim} end 2016 (%)	1.2	1.3	1.1	1.3	1.4	1.1	1.2	1.2
falling below <i>B</i> _{lim} end 2017 (%)	2.1	2.1	2.1	2.2	2.5	2.0	2.2	2.2
falling below <i>B</i> _{lim} end 2018 (%)	3.3	3.4	3.5	3.3	3.7	3.3	3.5	3.4
exceeding Z_{msy} in 2016 (%)	21.7	24.5	26.6	28.2	30.7	32.3	34.7	36.9
exceeding Z_{msy} in 2017 (%)	23.0	26.3	27.6	29.4	31.9	33.4	36.8	38.8
exceeding Z _{msy} in 2018 (%)	23.8	27.3	28.8	31.0	33.2	35.3	37.8	40.0

In the medium term, model results estimate that catches up to 90 000 t/yr could be associated with a slowly decreasing stock (Fig. 3.10). At the present state the biomass is 23% above its B_{msy} , and therefore less productive. Catches up to 90 000 t/yr will reduce the biomass in medium term, but the biomass might become more productive.

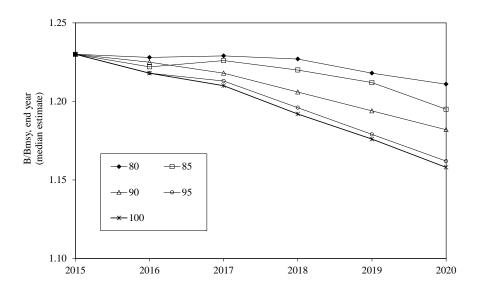

Fig. 3.10. Northern shrimp in Subarea 1 and Canadian SFA1: median estimates of biomass trajectory for 5 years with annual catches at 80–100 Kt and an 'effective' cod stock assumed at 55 Kt.

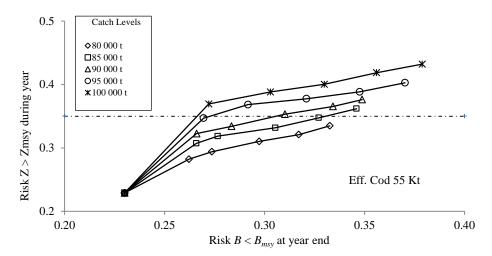

Fig. 3.11. Northern shrimp in Subarea 1 and Canadian SFA1: Risks of transgressing mortality and biomass precautionary limits with annual catches at 80–100 Kt projected for 2016–20 with an 'effective' cod stock assumed at 55 Kt.

Medium-term projections were summarised by plotting the risk of exceeding Z_{msy} against the risk of falling below B_{msy} over 5 years for 5 catch levels, considering an 'effective' cod stock close to the 2015 estimate (Fig. 3.11). The mortality risk depends immediately upon the assumed future catch and cod-stock levels, but changes little with time. For catches of 90 Kt to 95 Kt the mortality risk is 32–38% and nearly constant over the projection period. The immediate biomass risk is relatively insensitive to catch level but changes with time. At catch levels that permit rapid growth in biomass (90Kt), biomass risk decreases with time, but at catch levels that allow only slow growth, the compounding of uncertainties eventually causes estimated biomass risk to increase. This is aggravated by the high cod-stock biomass for which predictions are being made, the uncertainty associated with predation by cod being large in the present assessment.

287

f) Research Recommendations

NIPAG **recommended** in 2012 that, for Northern shrimp off West Greenland (NAFO Subareas 0 and 1):

• given that the CPUE series for the Greenland sea-going and coastal fleets continue to agree while neither agrees with changes in the survey estimates of biomass since 2002, possible causes for change in the relationship between fishing efficiency and biomass should be investigated;

STATUS: In progress; this recommendation is reiterated.

• the relationship between estimated numbers of small shrimps and later estimates of fishable biomass should be investigated anew.

STATUS: In progress; this recommendation is reiterated.

In 2014:

NIPAG **recommends** that the structure and coding in the assessment model of the relationship between cod biomass, shrimp biomass and estimated predation should be reviewed, including an analysis of the error variation.

STATUS: Ongoing. A correction to the coding of the model was implemented in the 2015 assessment, but further investigations of the treatment of the error variance is indicated.

NIPAG **recommends** that further refinements to the "partial MIXing" method of estimating numbers at age should be explored.

STATUS: In progress; this recommendation is reiterated.

In 2015:

Survey trends inshore and offshore are divergent and NIPAG **recommends** *exploration of the nature and implications of this divergence.*

37. Northern shrimp off East Greenland in ICES Div. XIVb and Va

Background documentation (equivalent to stock annex) is found in SCR Docs. 03/74, 15/45, 15/50.

a) Introduction

Northern shrimp off East Greenland in ICES Div. XIVb and Va is assessed as a single population. The fishery started in 1978 and, until 1993, occurred primarily in the area of Stredebank and Dohrnbank as well as on the slopes of Storfjord Deep, from approximately 65°N to 68°N and between 26°W and 34°W.

A multinational fleet exploits the stock. During the recent ten years, vessels from Greenland, EU, the Faroe Islands and Norway have fished in the Greenland EEZ. Only Icelandic vessels are allowed to fish in the Icelandic EEZ. At any time access to these fishing grounds depends strongly on ice conditions.

In 1993 a new fishery began in areas south of 65°N down to Cape Farewell. From 1996 to 2005 catches in this area accounted for 50 - 60% of the total catch. In 2006 and 2007 catches in the southern area only accounted for 25% of the total catch, decreasing to about 10% from 2008 - 2012. No fishery has taken place in the Southern area since then.

In the Greenland EEZ, the minimum permitted mesh size in the cod-end is 44 mm, and the fishery is managed by catch quotas allocated to national fleets. In the Icelandic EEZ, the mesh size is 40 mm and there are no catch limits, however there have been no catches by Iceland after 2005. In both EEZs, sorting grids with 22-mm bar spacing to reduce by-catch of fish are mandatory. Discarding of shrimp is prohibited in both areas.

As the fishery developed, catches increased rapidly to more than 15 000 tons in 1987-88, but declined thereafter to about 9 000 t in 1992-93. Following the extension of the fishery south of 65°N catches increased again reaching 11 900 t in 1994. From 1994 to 2003 catches fluctuated between 11 500 and 14 000 t (Fig. 4.1). Since 2004 the catches decreased continually from 10 000 tons. Catches have been between 1200 and 2100 t from 2011 to 2013. In 2014 and the first half of 2015 catches of about 600 t has been obtained.

¹Catches until June 2015

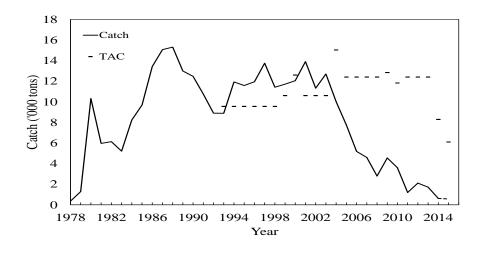

Fig. 4.1. Shrimp in Denmark Strait and off East Greenland. Catch and TAC (2015 catches until June).

b) Input Data

i) Commercial fishery data

Fishing effort and CPUE. Data on catch and effort (hours fished) on a haul by haul basis from logbooks from Greenland, Iceland, Faroe Islands and EU since 1980 and from Norway since 2000 are used. Until 2005, the Norwegian fishery data was not reported in a compatible format and were not included in the standardized catch rates calculations. In 2006 an evaluation of the Norwegian logbook data from the period 2000 to 2006 was made and since then these data have been included in the standardized catch rate calculations. Since 2004 more than 60% of all hauls were performed with double trawl, and both single and double trawl are included in the standardized catch rate calculations.

Catches and corresponding effort are compiled by year for two areas, one area north of 65°N and one south thereof. Standardised Catch-Per-Unit-Effort (CPUE) was calculated and applied to the total catch of the year to estimate the total annual standardised effort. Catches in the Greenland EEZ are corrected for "overpacking" up to 2004 (SCR Doc. 03/74).

The overall CPUE index declined continuously from 1987 to 1993. From 1993 to 1999 the overall CPUE index increased. The overall CPUE index remained relatively high from 2000-2008, nearly doubled in 2009, declined until 2014 and is at the same level in 2015 as in 2014 (Fig. 4.2). As most of the fishing has been conducted in the northern area the overall CPUE index is dominated by the CPUE index for the area north of 65°N (Fig. 4.2 and Fig. 4.3).

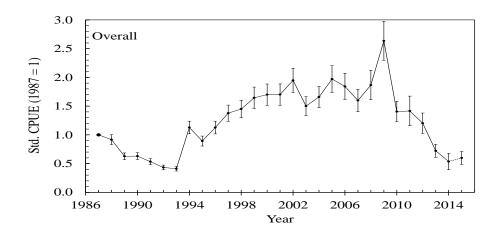

Fig. 4.2. Shrimp in Denmark Strait and off East Greenland: annual standardized CPUE-indices (1987 = 1) with \pm 1 SE combined for the total area (2015 catches until June).

North of 65°N standardized catch rates declined continuously from 1987 to 1993. From 1993 to 1999 catch rates increased and remained relatively high from 2000-2008. In 2009 the catch rates nearly doubled but have since decreased and have since 2013 been close to the lowest level seen in the time series (Fig. 4.3).

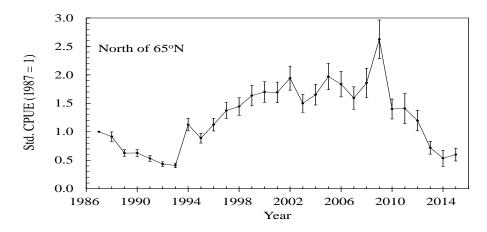

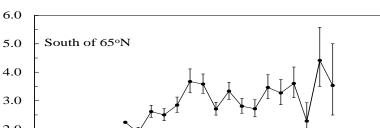

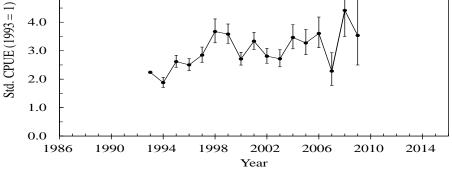

Fig. 4.3. Shrimp in Denmark Strait and off East Greenland: annual standardized CPUE (1987 = 1) with ± 1 SE fishing north of 65°N (2015 catches until June).

In the southern area a standardized catch rate series increased until 1998, and has since then fluctuated without a trend (Fig. 4.4). No index for the southern area was calculated since 2010 due to a low number of hauls.

Shrimp in Denmark Strait and off East Greenland: annual standardized CPUE (1993 = 1) Fig. 4.4. with ± 1 SE fishing south of 65°N (no data for the area since 2010).

Standardized effort indices (catch divided by standardized CPUE) as a proxy for exploitation rate for the total area shows a decreasing trend since 1993. Recent levels are the lowest of the time series (Fig. 4.5).

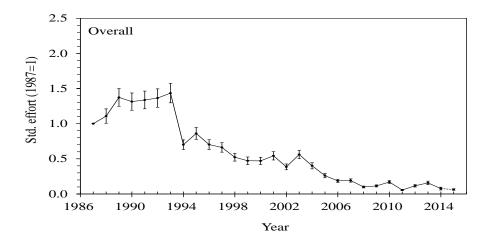

Fig. 4.5. Shrimp in Denmark Strait and off East Greenland: annual standardized effort indices, as a proxy for exploitation rate (± 1 SE; 1987 = 1), combined for the total area (2015 effort until June).

ii) Research survey data

Stratified-random trawl surveys have been conducted to assess the stock status of northern shrimp in the East Greenland area since 2008. The main objectives were to obtain indices for stock biomass, abundance, recruitment and demographic composition. The area was also surveyed in 1985-1988 (Norwegian survey) and in 1989-1996 (Greenlandic survey). The historical survey is not directly comparable with the recent survey due to different areas covered, survey technique and trawling gear.

Biomass. The survey biomass index decreased from 2009 to 2012 and have since then remained at a low level (Fig. 4.6).

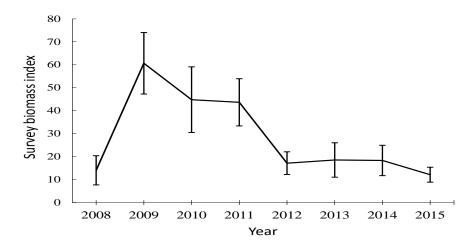

Fig. 4.6. Shrimp in Denmark Strait and off East Greenland: Survey biomass index from 2008-2015 (\pm 1 SE).

The surveys conducted since 2008 indicate that the shrimp stock is concentrated in the area north of 65°N (Fig. 4.7).

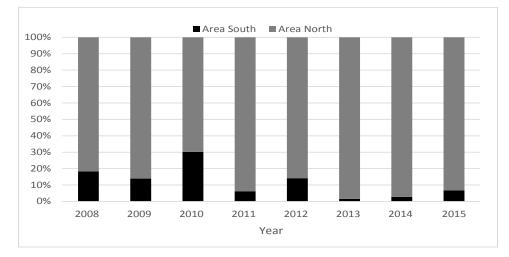

Fig. 4.7. Shrimp in Denmark Strait and off East Greenland: Distribution of Survey biomass North and South of 65°N (%) from 2008 - 2015.

Stock composition.

The demography in East Greenland is dominated by a large proportion of females and shows a paucity of males smaller than 20 mm CL (Fig. 4.7).

Scarcity of smaller shrimp in the survey area stresses that the total area of distribution and recruitment patterns of the stock are still unknown.

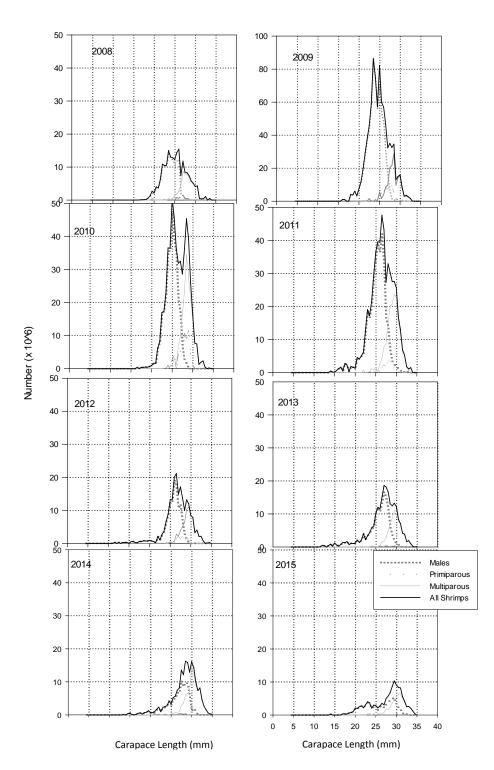

Fig.4.7. Shrimp in Denmark Strait and off East Greenland. Numbers of shrimp by length group (CL) in the total survey area in 2008 - 2015 (Please note that the scale in the figure for 2009 differs from other years).

294

c) Assessment Results

CPUE: The overall CPUE index remained at a high level from 2000-2008, nearly doubled in 2009, but has been declining since, and have since 2013 been close to the lowest level seen in the time series.

Recruitment. No recruitment estimates were available.

Biomass. The survey biomass index has decreased by around 80% since 2009.

Exploitation rate. Since the mid-1990s the exploitation rate index has decreased, reaching the lowest levels seen in the time series.

State of the stock. The stock size remained at a very low level in 2015 despite several years of very low exploitation rates.

d) Reference points

NIPAG is unable to determine precautionary reference points at this time.

. A.A.

38. Northern shrimp in Skagerrak and Norwegian Deep (ICES Div. IIIa and IVa East) – ICES Stock

Background documentation (equivalent to stock annex) is found in SCR Doc. 08/75; 13/68, 74; 15/56, 57, 58, 59, 60

a) Introduction

The shrimp in the northern part of ICES Div. IIIa (Skagerrak) and the eastern part of Div. IVa (Norwegian Deep) is assessed as one stock and is exploited by Norway, Denmark and Sweden. The Norwegian and Swedish fisheries began at the end of the 19th century, while the Danish fishery started in the 1930s. All fisheries expanded significantly in the early 1960s. By 1970 the landings had reached 5 000 t and in 1981 they exceeded 10 000 t. Since 1992 the shrimp fishery has been regulated by a TAC, which was around 16 500 t in 2006-2009, thereafter declined steadily to only 9 500 t in 2013 and 2014, but increased to 10 900 t in 2015 (Fig. 5.1, Table 5.1). In the Swedish and Norwegian fisheries approximately 50% of catches (large shrimp) are boiled at sea, and almost all catches are landed in home ports. Since 2002, an increasing number of the Danish vessels are boiling the shrimp on board and landing the product in Sweden to obtain a better price. The rest is landed fresh in home ports. The overall TAC is shared according to historical landings, giving Norway 58-60%, Denmark 26-28%, and Sweden 14% in 2011 to 2015. The recommended TACs were until 2002 based on catch predictions. In 2003, the cohort-based assessment was abandoned and no catch predictions were available. The recommended TACs were therefore based on perceived stock development in relation to recent landings until 2013, when an assessment based on a stock production model was introduced for this stock. In 2015, a length based model was run in parallel. The shrimp fishery is also regulated by mesh size (35 mm stretched), and by restrictions in the amount of landed bycatch. Since February 1st 2013, it has been mandatory to use grids in all *Pandalus* trawl fishery in Skagerrak, and since January 1st 2015, the same regulation applies to the North Sea south of 62 °N (see section on Bycatch and ecosystem effects below).

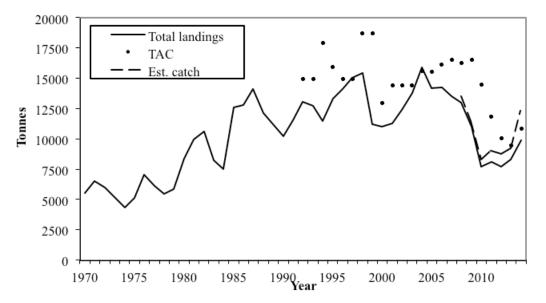

Fig. 5.1. Northern shrimp in Skagerrak and Norwegian Deep: TAC, total landings by all fleets, and total estimated catch including estimated Swedish discards for 2008-2014, and Norwegian and Danish discards for 2009-2014.

Table 5.1.Northern shrimp in Skagerrak and Norwegian deep: TACs, landings, and estimated discards
and catches (t).

297

The Danish and Norwegian fleets have undergone major restructuring during the last 25 years. In Denmark, the number of vessels targeting shrimp has decreased from 138 in 1987 to only 10 in 2014. The efficiency of the fleet has increased due to the introduction of twin trawls and increased trawl size (SCR Doc. 15/60).

In Norway the number of vessels participating in the shrimp fishery has decreased from 423 in 1995 to 203 in 2014. Twin trawls were introduced around 2002, and the use is increasing. In 2011-2014 twin trawls were used by more than half of the Norwegian trawlers larger than 15 meters (SCR Doc. 15/57).

The Swedish specialized shrimp fleet (landings of shrimp ≥ 10 t/yr) has decreased from more than 60 vessels in 1995-1997 to 33 in 2014. There has not been any major change in single trawl size or design, but during the last nine years the twin trawlers have increased their landings from 7 to over 50% (recent 4 years) of total Swedish *Pandalus* landings (SCR Doc. 15/60).

Landings and discards. Total landings have varied between 7 500 and 16 000 t during the last 30 years. In the total catch estimates the boiled fraction of the landings has been raised by a factor of 1.13 to correct for weight loss caused by boiling. Total catches, estimated as the sum of landings and discards, decreased from 2008 to 2012, to 8 800 t, but increased to 9 300 t in 2013 and to 12 300 t in 2014 (Table 5.1 and Fig. 5.1).

Shrimps can be discarded for one of two reasons: 1) shrimp < 15 mm CL are not marketable (and in Norway, not legal to land), and 2) to replace medium-sized, lower-value shrimps with larger and more profitable ones ("high-grading"). The Swedish fishery has often been constrained by the national quota, which may have resulted in high-grading. Based on on-board sampling by observers, discards in the Swedish fisheries have been estimated to be between 12 and 31% of total catch for 2008 -2014, and Danish discards have been estimated to be between 2 and 18% for 2009-2014. Discarding is illegal in Norwegian waters, but there are no observer data. From 2009 onwards Norwegian discards in Skagerrak have been estimated by applying the Danish discards-to-landings ratio to the Norwegian landings. Norwegian discards are probably underestimated as the proportion of boiled large shrimp in the Norwegian landings is larger than in the Danish landings (SCR Doc. 15/57). Assuming, in the absence of observer data, that Norwegian discards from the Norwegian Deep are mainly made up of shrimp < 15 mm CL, discards from this area are estimated as the weight of catches of shrimp < 15 mm CL, obtained from length distributions of catches and mean weight at length.

Bycatch and ecosystem effects. Shrimp fisheries in the Norwegian Deep and Skagerrak have bycatches of 10-22% (by weight) of commercially valuable species, which are legal to land if quotas allow (Table 5.2). Since 1997, trawls used in Swedish national waters must be equipped with a Nordmøre grid, with a bar spacing of 19 mm, which excludes fish > approx. 20 cm length from the catch. Landings delivered by vessels

using grids comprise 95-99% shrimp compared to only 60-84% in landings from trawls without grids (Table 5.2). Following an agreement between EU and Norway, the Nordmøre grid has been mandatory since 1st February 2013 in all shrimp fisheries in Skagerrak (except Norwegian national waters within the 4 nm limit). From 1st of January 2015, the grid has also been mandatory in shrimp fisheries in the North Sea south of 62 °N. If the fish quotas allow, it is legal to use a fish retention device of 120 mm square mesh tunnel at the grid's fish outlet.

The use of a fish retention device also prevents the escape of non-commercial species. Deep-sea species such as argentines, roundnose grenadier, rabbitfish, and sharks are frequently caught in shrimp trawls in the deeper parts of Skagerrak and the Norwegian Deep. No quantitative data on this mainly discarded catch is available and the impact on stocks is difficult to assess.

Catches of fish in the Campelen-trawl of the Norwegian annual shrimp survey covering Skagerrak and the Norwegian Deep (see below) give an indication of the level of bycatch of non-commercial species in shrimp trawls (Table 5.3). The large inter-annual variation in the predator biomass index is mainly due to variations in the indices for saithe and roundnose grenadier, which in some years are important components. These contributions depend upon which survey stations are trawled as the largest densities of saithe are found in shallow water and roundnose grenadier is found in deep water. An index without hese species (given at the bottom of Table 5.3) has been at the same level for the last 10 years. The peak in 2013 was due to a high abundance of blue whiting.

b) Input Data

i) Fishery data

Danish, Swedish and Norwegian catch and effort data from logbooks have been analyzed and standardized (SCR Doc. 08/75; 15/57, 60).

There was an increasing trend in the standardized LPUE for all three series from 2000 to 2007 followed by a decreasing trend until 2012. All three series have increased since 2013 (Fig. 5.2).

Time series of standardized effort indices have been fluctuating without any clear trend since the mid-1990s (Fig. 5.3).

300

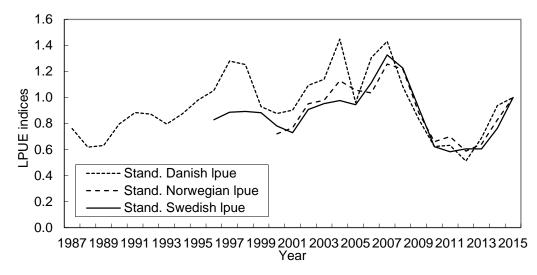

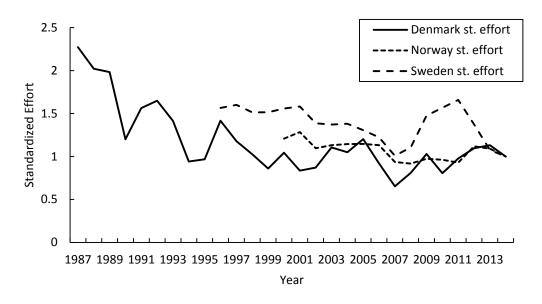

Fig. 5.2. Northern shrimp in Skagerrak and Norwegian Deep: Danish, Norwegian and Swedish standardized LPUE until 2015. 2015 data are preliminary. Each series is standardized to its last year.

ii) Sampling of catches.

Length frequencies of the catches from 1985 to 2014 (SCR Doc. 15/57, 60) have been obtained by sampling. The samples also provide information on sex distribution and maturity. Numbers at length are input data to the newly developed length-based assessment model for this stock (see below).

iii) Survey data

The Norwegian shrimp survey went through large changes in vessel, gear and timing in 2003-06, resulting in four indices (SCR Doc. 15/58): Survey 1: October/November 1984-2002 with Campelen trawl; Survey 2:

October/November 2003 with shrimp trawl 1420; Survey 3: May/June 2004-2005 with Campelen trawl; and Survey 4: January/February 2006-present with Campelen trawl.

Due to time and weather restrictions not all survey strata were covered in all years. The following years have missing strata: 1984, 1986, 2002, 2006, 2012, 2014, and 2015 (Fig. 5.4). The index of total biomass for these years has been corrected by applying the missing strata's mean portion of the total biomass (averaged over all years with complete coverage) to the total biomass of the year. However, total numbers at length have not yet been corrected, which means that the length-based model (see below) uses uncorrected survey data while the surplus production model (see below) uses corrected data.

The biomass index increased from 1988 to the first series's maximum in 1997 (Fig. 5.4). A decrease in 1998-2000 was followed by an increase in 2001-2002, when this series was discontinued. "Series 2" comprises a single point in 2003. The 2004 and 2005 values from the third series were similar. The fourth series peaked in 2007 and after that showed a steady decline to a minimum in 2012. Thereafter the index has increased.

A recruitment index has been calculated for the fourth series as the abundance of age 1 shrimp. The recruitment index value declined from 2007 to 2010, fluctuated at a low level until 2013 and thereafter increased to the time series' highest value in 2014 (Fig. 5.5). In 2015, the abundance of age 1 shrimp was again low.

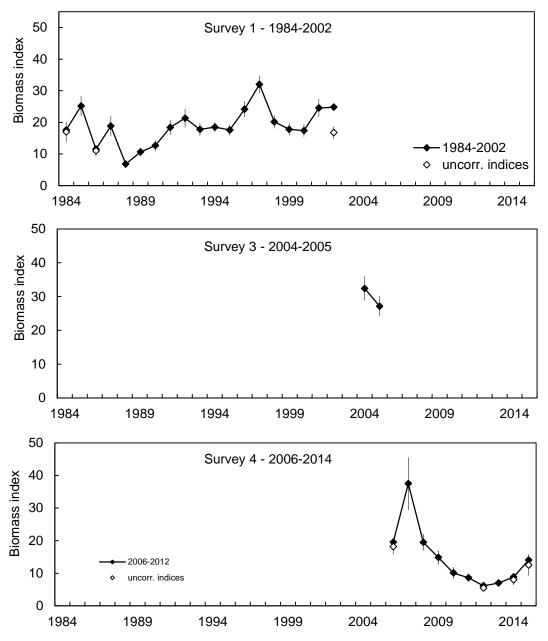

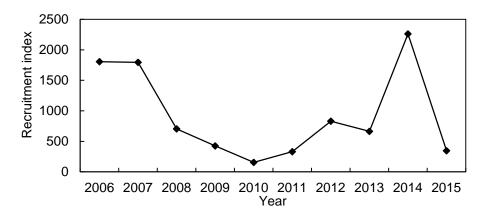

Fig. 5.4. Northern shrimp in Skagerrak and Norwegian Deep: Estimated survey biomass index in 1984 to 2015. The point estimate of 2003 is not shown.

303

c) Assessment models

In the benchmark of this stock (ICES, 2013a), a length-based model (LBM) and a surplus production model (SPM) were considered: "While both the LBM and the SPM models gave similar results and were considered capable of forming the basis for the stock assessment, the Benchmark preferred the length-based model because it made more use of the available data from the surveys and the catches and because it was relatively easy to update and run. However it was decided that the SPM should be run alongside the LBM, at least initially, to provide reassurance that the assessments from the two models continued to remain consistent". The LBM was not fully operational in 2013 and 2014, but for this year's assessment, both models produced full assessment outputs and were considered in parallel. Both models gave similar results in terms of biomass dynamics but diverged in estimation of recent F values and in estimation of stock status relative to reference points and hence in derived advice.

The WG noted significant progress in the completion of the LBM as an assessment tool, so that it now produces all the output needed to provide ICES standard advice, but never the less decided to use the SPM as the primary basis for this year's advice and use the LBM for supportive information.

Rationale:

A very high LBM-estimate of F_{1-3} in 2014 was of some concern to the WG. Although a substantially increasing F for the larger shrimp up to 2014 is to be expected from five preceding years of historically low recruitment to the fishable biomass, the 2014 estimate of F_{1-3} of 1.45 is considered a possible over-estimation. The retrospective plots show no serious problems with regards to the SSB and the R, whereas for F there has been some retrospective pattern (Fig. 5.6). Particularly the high estimate for 2012 was considerably revised down. It is unknown whether this situation will apply also to the high 2014 estimate.

A.A.

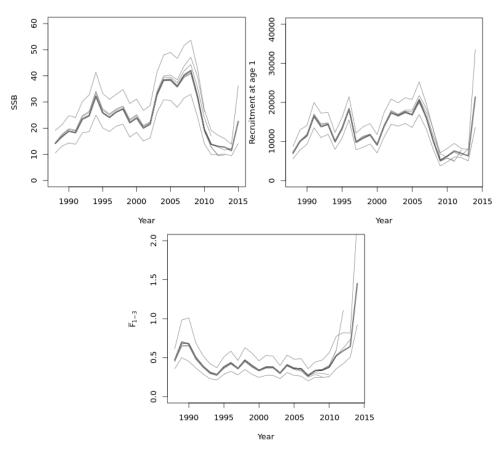

Fig. 5.6. Northern shrimp in Skagerrak and Norwegian Deep: Estimates of SSB (t), recruits (thousands) and F_{1-3} from the length-based model. Light grey lines represent 95% confidence limits.

The WG also noticed that LBM-estimates of commercial catches by length fit the actual observations better than the model-estimates of survey catch. More specifically the model frequently under-estimates peaks in the survey observations of the youngest age-classes and also often estimates a double peak in the 15-20mm range, while the data show a single peak. Possible explanations of this are that the growth rates of the model are incorrectly defined (von Bertalanffy growth relationship), selectivity is modelled incorrectly, and/or natural mortality is poorly defined. These improvement potentials of the LBM were also highlighted in an ad hoc external review of the model (Annex II).

Based on the above considerations it was decided to use the SPM as primary basis for this year's advice and use the LBM for supportive information, until the potential of alternative growth rate and selectivity assumptions have been explored.

It is noted that the SPM depends on ecosystem state to remain within the range of the modelled historical period. If e.g. predation or recruitment were to increase rapidly outside the range previously experienced by the shrimp stock within the modelled period, the shrimp stock might decrease or increase in size more than the model results have indicated as likely. The LBM would in theory be more precise in making short-term predictions as it explicitly keeps account of the incoming recruitment to the fishery. The LBM will however, also be sensitive to regime shifts through its assumptions about M. While the SPM might not be the perfect model for this stock the diagnostics and conclusions made at the recent benchmark (ICES, 2013a) still hold.

d) Assessment Results

i) Length-based model (SCR Doc. 15/056)

Historical stock trends and recruitment

The spawning stock biomass (SSB) has been variable over the assessment period 1988 to 2015 (Fig. 5.7). From 2001, SSB increased to over 42 000 t in 2008, after which it decreased to about 11 000 t in 2014. This is the lowest observed SSB in the times series. SSB has increased to about 23 000 t in 2015, but the large uncertainties around the most recent estimates should be taken into account when deciding on the MSY.

Recruitment (R) has similar to the SSB been variable over the assessment period 1988 to 2015 (Fig. 5.7). A series of low recruitment years between 2009 and 2015, with the exception of year 2014, should be noted. During this period of low recruitment the estimates of SSB were also historically low and below B_{lim} . The uncertainties around the estimate of recruitment in 2015 were exceptionally large. The reason for this is that the model has not yet seen the recruits in the fishery data (data until 2014), only in the survey data (January 2015).

Fishing mortality (F) for ages 1 to 3 has remained relatively stable since the beginning of the 1990s to about 2010, after which F has increased steeply to 1.45 in 2014 (Fig. 5.7). The uncertainties around the most recent estimates, in particular in 2014, should be noted.

A.A.

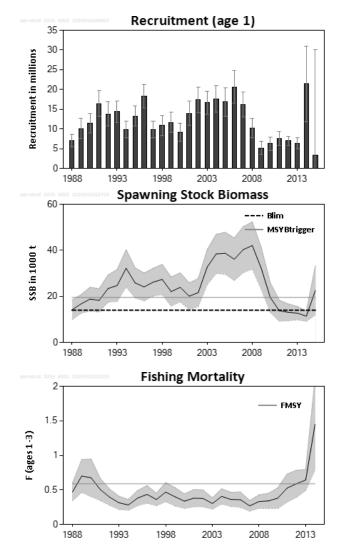

Fig. 5.7. Northern shrimp in Skagerrak and Norwegian Deep: Summary of the stock assessment of LBM. The 2.5% and 97.5% quantiles are included in all three figures.

Reference points

The reference points are defined based on a WG-definition of the *Pandalus* stock as being medium-lived (Table 5.4). F_{MSY} was defined as $F_{0.1}$, estimated from a yield per recruit curve as no stock-recruitment relationship was identified (Fig. 5.8). B_{lim} was defined as the lowest SSB (nearest thousand tonnes) of the time series, above which recruitment did not seem to be negatively influenced by SSB (14 000 t). B_{pa} was set at B_{lim} * 1.4 (= 19 600 t). MSY $B_{trigger}$ is set equal to B_{pa} . These reference points were to some extent considered provisional and possibilities for establishing new reference points based on stock-recruitment relationship (using standard ICES methodology) will be explored next year.

Framework	Reference point	Value	Technical basis	Source
MSY	MSY B _{trigger}	19600	$B_{trigger} = B_{pa}$	NIPAG report, ICES
approach	Fmsy	0.59	$F_{0.1}$ from the yeild per recruit curve	NIPAG report
	B _{lim}	14000	Defined as the lowest SSB of the time series, above which recruitment does not seem to be negatively impaired by the level of SSB (14 000t).	NIPAG report
Precautionary approach	B _{pa}	19600	<i>B_{lim}</i> *1.4	NIPAG report; ICES
	F _{lim}	Not defined		
	F _{pa}	Not defined.		
Management	SSB _{MGT}		There is no management plan for this stock	
plan	F _{MGT}		There is no management plan for this stock

ii) Stock production model fitted by Bayesian methods using fishery catch and effort data and data from the Norwegian shrimp survey (SCR Doc. 15/059).

The input series of biomass indices span 1984-2015. Since the late 1980s the stock has varied with a slightly increasing trend until 2006 when it started to decline (Fig. 5.9). This is similar to the development of SSB according to the LBM (Fig. 5.7). The median 2015 estimate is above B_{msy} (Table 5.7). The estimated risk of stock biomass being below $B_{trigger}$ in 2015 was 0% and of being below B_{lim} , 0% (Table 5.7).

Median estimate of fishing mortality has remained below F_{msy} since 1989 (Fig. 5.10). There is a 2% risk of F_{2015} being above F_{msy} (Table 5.7).

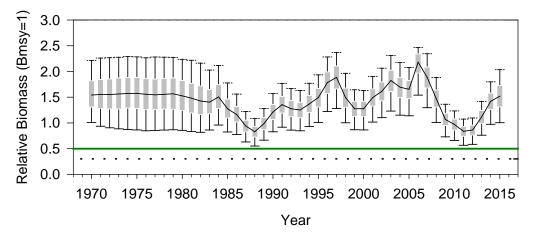

Fig. 5.9. Northern shrimp in Skagerrak and Norwegian Deep: Estimated time series of relative biomass (Bt/Bmsy) 1970-2015. The solid black line is the median; boxes represent quartiles; the whiskers cover the central 90% of the distribution. Dashed black line represents *Blim*. Green line represents $B_{trigger}$.

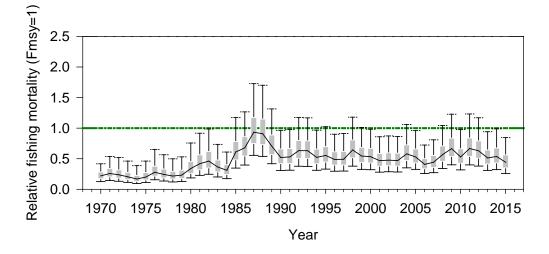

Fig. 5.10. Northern shrimp in Skagerrak and Norwegian Deep: Estimate of relative fishing mortality (F_t/F_{msy}) 1970-2015. The solid black line is the median; boxes represent quartiles; the whiskers cover the central 90% of the distribution. Green line marks F_{msy} .

Status	2014	2015*
Risk of falling below B_{lim} (0.3 B_{MSY})	0%	0%
Risk of falling below <i>Btrig</i> $(0.5B_{MSY})$	0%	0%
Risk of exceeding F_{MSY}	5%	2%
Stock size (B/Bmsy), median Fishing mortality (F/Fmsy),	1.41	1.50
median	0.54	0.44
Surplus production (% of MSY)	84%	75%

*Predicted catch = TAC

e) Stock development and biological reference points

Reference points. In 2009, ICES adopted a "Maximal Sustainable Yield (MSY) framework" (ACOM. ICES Advice, 2013. Book 1. Section 1.2) for deriving advice. It considers two reference points: F_{msy} and $B_{trigger}$. In keeping with the reference points developed in 2006 and 2010 for the Barents Sea shrimp stock, 50% B_{msy} was adopted as $B_{trigger}$ (NIPAG, 2006). Under the ICES PA two reference points are required; B_{lim} and B_{pa} . Again in line with the Barents Sea shrimp stock, B_{lim} was set at 30% B_{msy} (NIPAG, 2006). B_{pa} is not considered relevant in the presence of a risk analysis. F_{lim} is equal to $1.7F_{msy}$ – the fishing mortality that drives the biomass to B_{lim} .

Projections. Given a catch of 12 340 t in 2014 and assuming a 2015 catch of 10 900 t (TAC), catch options from 14 000 t to 24 000 t were evaluated for 2016. Under all these catch options the risk of going below B_{lim} is <1%. Catches of up to 20 000 t have a <50% risk of exceeding F_{msy} and a <1% risk of falling below $B_{trigger}$ (Table 5.8).

	Catch option 2016 (ktons)					
	14	16	18.5	20	21.5	24
Risk of falling below B_{lim} (0.3 B_{msy})	0%	0%	0%	0%	0%	0%
Risk of falling below B_{trig} (0.5 B_{msy})	0%	0%	0%	0%	0%	0%
Risk of exceeding <i>F</i> _{msy}	12%	19%	28%	41%	50%	63%
Risk of exceeding <i>F</i> _{lim}	1%	2%	5%	7%	12%	17%
Stock size (B/B_{msy}), median	1.42	1.40	1.38	1.33	1.31	1.28
Fishing mortality (F/F_{msy}) ,	0.60	0.69	0.79	0.91	1.00	1.14
Productivity (% of MSY)	82%	84%	85%	89%	90%	92%

Table 5.8. Northern shrimp in Skagerrak and Norwegian Deep: Catch options for 2016.

Comparison of Assessment Models

Two models are used in the assessment of this stock. One is length/age based, uses data on numbers at length from catches and survey, and tracks the age cohorts into which those numbers are converted. The other is a surplus-production model which considers only the dynamics of the stock biomass using series of indicators of biomass.

- 1. The models agree that SSB decreased fairly drastically since about 2006, but with an increasing trend the most recent years.
- 2. The length-based model measures a rapid recent increase in fishing mortality, not evident in the results of the surplus-production model.

3. The length-based model takes into account, in its predictions, the recent (2015) low observation of age-1 shrimps in the stock, which the surplus-production model is not constructed to be able to do.

311

- 4. The length-based model estimates current SSB to be above B_{lim} for the first time since 2009 while the surplus production model estimates SSB above $B_{trigger}$ throughout the series.
- 5. The length-based method estimates short-term yield of 11 920 t at F_{msy} , while the surplus production model would yield 18 500 t.

Summary of Assessment (SPM)

Mortality. Fishing mortality has remained below F_{msy} since 1990. There is a 2% risk of F_{2015} being above F_{msy} .

Biomass. Stock biomass has been above $B_{trigger}$ throughout the history of the fishery. The risk that the biomass at the end of 2015 is below $B_{trigger}$ is less than 1%.

Recruitment. The abundance of age-1 shrimp in the survey catches was low in 2009 and 2011, just below the mean in 2012-13 and record high in 2014. The 2015 value is low.

State of the Stock. The stock declined from 2006 to 2011, followed by an increase from 2011 to 2015. It is estimated to be well above $B_{trigger}$.

Yield. Catch options up to 18 500 t/yr for 2016 have a risk less than 30% of exceeding F_{msy} and less than 5% of exceeding F_{lim} .

f) Management Recommendations

NIPAG **recommends** that, for shrimp in Skagerrak and Norwegian Deep:

• Sorting grids should be implemented in the Norwegian Deep in addition to the Skagerrak.

STATUS: Sorting grids are implemented since 1st January 2015.

• Norwegian vessels between 12 and 15 m in the Norwegian Deep should be required to complete and provide log books.

g) Research Recommendations

There were no research recommendations for shrimp in Skagerrak and the Norwegian Deep.

h) Research Recommendations from the 2010-2014 meetings

• In the length-based model, explore the replacement of 'weight at age' with 'weight at length' data from the fishery

STATUS: 'weight at age' data from the fishery have been replaced with 'weight at length' data to improve model fit.

• the Norwegian shrimp survey should be extended east to cover important shrimp grounds in Swedish waters.

STATUS: Five trawl stations in Swedish national waters were covered by the survey in January 2015.

• the results of the current assessment should be compared with those of an updated run including survey data collected early in the following year.

STATUS: No progress has been made. NIPAG reiterates this recommendation.

• the Stochastic assessment model as described in SCR Doc.10/70 should be implemented and MSY reference points should be established.

STATUS: The benchmark assessment which was finalized during the NIPAG meeting in September 2013 chose the length based model as a basis for advice for the shrimp stock in Skagerrak and the Norwegian Deep. However, it was also decided that the Bayesian surplus production model would be run alongside the coming years, as a quality check of the forecast produced by the length based model.

• collaborative efforts should be made to standardize a means of predicting recruitment to the fishable stock.

STATUS: No progress has been made. NIPAG reiterates this recommendation.

• Differences in recruitment and stock abundance between Skagerrak and the Norwegian Deep should be explored.

STATUS: No progress has been made. NIPAG reiterates this recommendation.

• the ongoing genetic investigations to explore the relation/connection/mixing between the shrimp (stock units) in Skagerrak and the Norwegian Deep on the one hand and the Fladen Ground shrimp on the other hand should be continued until these relationships have been clarified.

STATUS: Results from the project "*Sustainable shrimp fishing in Skagerrak*" has detected weak genetic structure in the Skagerrak/North Sea region, primarily associated with fjords in the Skagerrak region (Knutsen *et al.* 2015). The shrimp in Skagerrak and the Norwegian Deep most likely comprise one single stock, which is in agreement with the oceanic current pattern in the area. The benchmark assessment in September 2013 concluded that we have one single shrimp stock in the Skagerrak and Norwegian Deep area. Genetic and time-series data (survey and LPUE) together with information on ocean currents in the North Sea suggest that the Fladen Ground shrimp constitute a separate population from the Skagerrak and Norwegian Deep stock (Knutsen *et al.* 2015).

Does population genetic structure support present management regulations of the northern shrimp (*Pandalus borealis*) in Skagerrak and the North Sea? ICES Journal of Marine Science 72(3): 863-871.

39. Northern Shrimp in the Barents Sea (ICES Sub-areas I and II)

Background documentation (equivalent to stock annex) is found in SCR Doc 15/52, 53, 54; 06/64, 08/56, 07/86, 07/75, 06/70.

a) Introduction

Northern shrimp (*Pandalus borealis*) in the Barents Sea and in the Svalbard fishery protection zone (ICES Sub-areas I and II) is considered as one stock (Fig. 6.1). Norwegian and Russian vessels exploit the stock in the entire area, while vessels from other nations are restricted to the Svalbard fishery zone and the "Loop Hole" (Fig. 6.1).

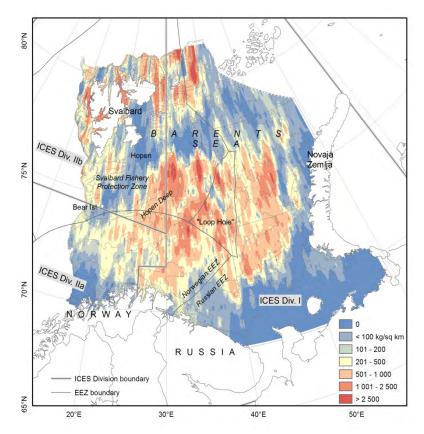

Fig. 6.1. Shrimp in the Barents Sea: stock distribution, mean density index (kg/km²), based on survey data.

Norwegian vessels initiated the fishery in 1970. As the fishery developed, vessels from several nations joined and the annual catch reached 128 000 t in 1984 (Fig. 6.2). In the recent 10-year period catches have varied between 20 000 and 40 000 t/yr, 50–90% taken by Norwegian vessels and the rest by vessels from Russia, Iceland, Greenland and the EU (Table 6.1).

There is no TAC established for this stock. The fishery is partly regulated by effort control, and a partial TAC (Russian zone only). Licenses are required for the Russian and Norwegian vessels. The fishing activity of these license holders is constrained only by bycatch regulations whereas the activity of third country fleets operating in the Svalbard zone is also restricted by the number of effective fishing days and the number of vessels by country. The minimum stretched mesh size is 35 mm. Bycatch is limited by mandatory sorting grids and by the temporary closing of areas where excessive bycatch of juvenile cod, haddock, Greenland halibut, redfish or shrimp <15 mm CL is registered.

Catch. Catches have ranged from 5 000 to 128 000 t/yr. (Fig. 6.2) since 1970. The most recent peak was seen in 2000 at approximately 83 000 t. Catches thereafter declined to about 20 000 t in 2013 and are predicted to remain at about that level in 2014 and 2015.

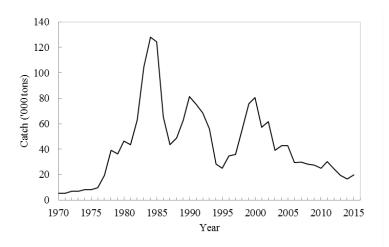

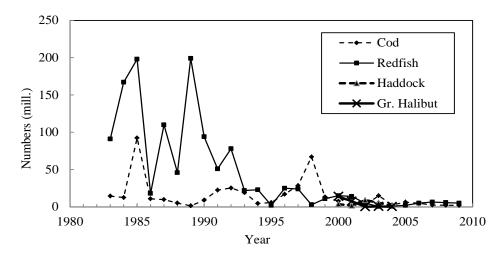

Fig. 6.2. Shrimp in ICES SA I and II: total catches 1970–2015 (2015 projected to the end of the year).

Discards and bycatch. Discard of shrimp cannot be quantified but is believed to be small as the fishery is not limited by quotas. Bycatch rates of other species are estimated from at-sea inspections and research surveys and are corrected for differences in gear selection pattern (SCR Doc. 07/86). Area-specific bycatch rates are then multiplied by the corresponding shrimp catches from logbooks to give an overall bycatch estimate.

Since the introduction of the Nordmøre sorting grid in 1992, only small individuals of cod, haddock, Greenland halibut, and redfish, in the 5–25 cm size range, are caught as bycatch. The bycatch of small cod ranged between 2 and 67 million individuals/yr and redfish between 2 and 25 million individuals/yr from about 1992 to 2010 while 1–9 million haddock/yr and 0.5–14 million Greenland halibut/yr were registered in 2000–2004 (Fig. 6.3). In recent years there has been a decline in bycatch owing to reduced effort in the shrimp fishery. Details of bycatch are no longer reported by the ICES Arctic Fisheries Working Group. NIPAG will update this bycatch information at its 2016 meeting.

315

b) Input Data

i) Commercial fishery data

A major restructuring of the shrimp fishing fleet towards fewer and larger vessels has taken place since the mid-1990s. At that time an average vessel had around 1 000 HP; 10 years later this value had increased to more than 6 000 HP (Fig. 6.4). Until 1996 the fishery was conducted using single trawls only. Double and triple trawls were then introduced. An individual vessel may alternate between single and multiple trawling depending on what is appropriate on given fishing grounds.

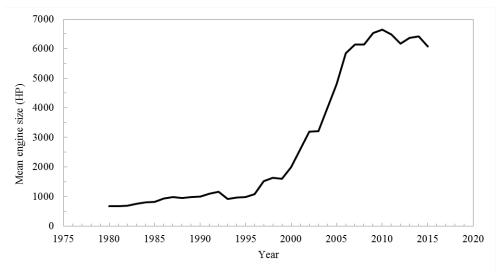

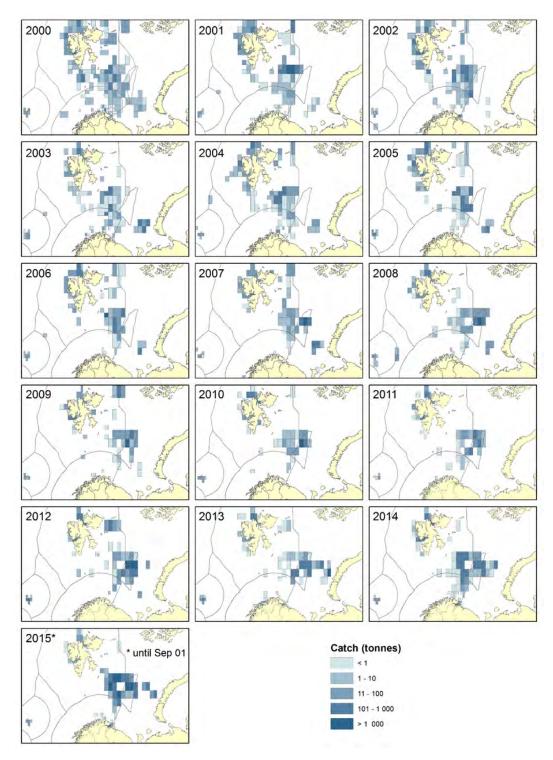

Fig. 6.4. Shrimp in ICES SA I and II: Mean engine power (HP) weighted by trawl-time, 1980–2015 (Norwegian data).

The fishery is conducted mainly in the central Barents Sea (Hopen Deep) and on the Svalbard Shelf along with the Goose Bank (south east Barents Sea) (Fig. 6.5). The fishery takes place throughout the year but may in some years be seasonally restricted by ice conditions. The lowest effort is generally in October through March, the highest in May to August.

Logbook data since 2009 show decreased activity in the Hopen Deep and around Svalbard, coupled with increased effort further east in international waters in the "Loop Hole" (Fig 6.5). Information from the

industry points to decreasing catch rates and more frequent area closures due to bycatch of juvenile fish on the traditional shrimp fishing grounds as the main reasons for the observed change in fishing pattern.

Fig. 6.5. Distribution of catches by Norwegian vessels since 2000 based on logbook information.

Norwegian logbook data were used in a multiplicative model (GLM) to calculate standardized annual catch rate indices (SCR Doc. 15/53). A new index series based on individual vessels rather than vessel groups was introduced in 2008 (SCR Doc. 08/56) in order to take into account the changes observed in the fleet. The GLM model used to derive the CPUE indices included the following variables: (1) vessel, (2) season (month), (3) area, and (4) gear type (single, double or triple trawl). The resulting series provides an index of the fishable biomass of shrimp \geq 17 mm CL, *i.e.* females and older males.

The standardized CPUE declined by 60% from a maximum in 1984 to the lowest value of the series in 1987 (Fig. 6.6). From then until 2011 it showed an overall increasing trend until 2005. Between 2005 and 2011 it fluctuated above the average of the time series, however after 2012 indices are below-average.

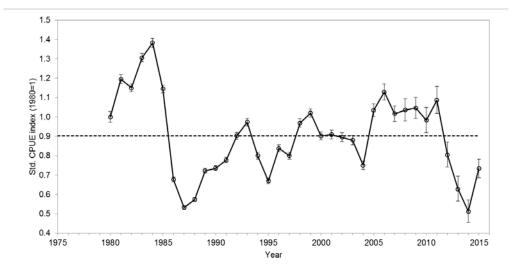

Fig. 6.6. Shrimp in ICES SA I and II: standardized CPUE based on Norwegian data. Error bars represent one standard error; dotted line is the mean of the series.

ii) Research survey data

Russian and Norwegian surveys have been conducted in their respective EEZs of the Barents Sea since 1982 to assess the status of the northern shrimp stock (SCR Doc. 06/70, 07/75, 14/51, 15/52). The main objectives have been to obtain indices for stock biomass, numbers, recruitment and demographic composition. In 2004, these surveys were replaced by a joint Norwegian-Russian "Ecosystem survey" which monitors shrimp along with a multitude of other ecosystem variables in the Barents Sea and around Svalbard (SCR Doc.14/55, 15/52).

Biomass. The Biomass indices of the Norwegian and Russian shrimp surveys (survey 1 and 2) varied without trend between 1982 and 2005 (Fig. 6.7). The Joint Russian-Norwegian Ecosystem Survey (survey 3) increased by about 66% from 2004 to 2006 and then decreased back to the 2004-value in 2008 (Fig. 6.7). The 2011 to 2013 values are back up close to that of 2006 while the 2014 value is down again from this level by about 25%

Due to heavy ice conditions the north-eastern part of the area was poorly covered and there were no hauls taken in stratum 3. For the 2004-2013 survey period this area accounts for on average 13% of the biomass (range: 8-27%). The 2014 biomass for area 3 was estimated by calculating the average ratio of biomass density in area 3 to biomass density in the remaining survey area for the 2009-2013 period and applying this average to the density of the 2014 surveyed area. Estimates of variance for area 3 was taken as the variance of the 2009-2013 estimates for area 3 (Table 4, SCR Doc. 15/052).

The geographical distribution of the stock in 2009-2014 was more easterly compared to that of the previous years (Fig. 6.8).

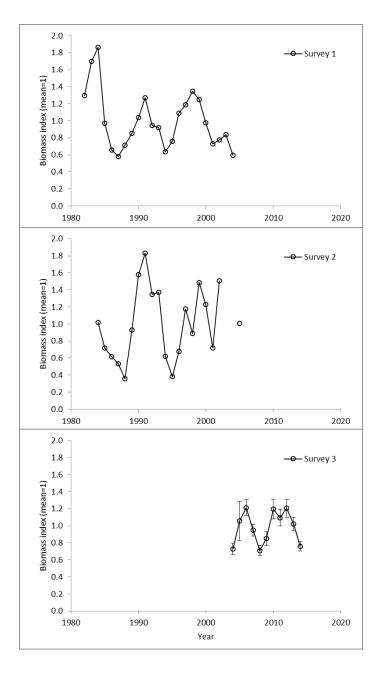

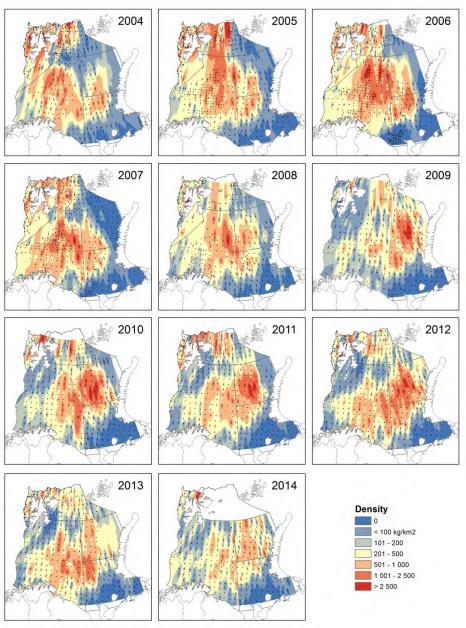

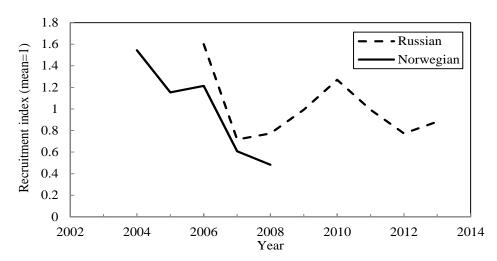

Fig. 6.7. Shrimp in ICES SA I and II: Indices of total stock biomass from the (1) 1982-2004 Norwegian shrimp survey, (2) the 1984-2005 Russian survey, and (3) the joint Russian-Norwegian ecosystem survey 2004-2014 (the 2015 survey data is not available at the time of the NIPAG meeting). Error bars represent one standard error.

319

Fig. 6.8. Shrimp in ICES SA I and II: Shrimp density (kg/km2) as calculated from the Ecosystem survey data 2004–2014 (no data for strata 3 due to ice conditions).

Recruitment indices. A recruitment index were derived from the overall size distributions based on Russian and Norwegian survey samples (SCR Doc. 14/55 and 15/52 respectively) as estimated abundances of shrimp at 13 to 16 mm CL. Shrimp at this size will probably enter the fishery in the following one to two years. This index has varied without trend (Fig. 6.9).

320

Fig. 6.9. Shrimp in ICES SA I and II: Index of recruitment: abundance of shrimp at size 13–16 mm CL based on Norwegian survey samples 2004-2008 and Russian survey samples 2006-2013.

Environmental considerations. Temperatures in the Barents Sea have been high since 2004, largely due to increased inflow of warm water masses from the Norwegian Sea. Shrimps are mainly caught in areas where bottom temperatures are above 0°C. Highest densities are observed between zero and 4°C, while the upper limit of their preferred temperature range appears to lie at about 6-8°C. The eastward shift in shrimp distribution in recent years may be associated with changes in temperature.

c) Estimation of Parameters

The modelling framework introduced in 2006 (SCR Doc. 06/64) was used for the assessment. Model settings were the same as ones used in previous years.

Within this model, parameters relevant for the assessment and management of the stock are estimated, based on a stochastic version of a surplus-production model. The model is formulated in a state-space framework and Bayesian methods are used to derive "posterior" probability density distributions of the parameters (SCR Doc. 15/54).

The model synthesized information from input priors, four independent series of shrimp biomass indices and one series of shrimp catch. The biomass indices were: a standardized series of annual fishery catch rates for 1980–2015 (Fig. 6.6, SCR Doc. 15/53); and trawl-survey biomass indices for 1982–2004, 1984–2005 and for 2004–2014 (Fig, 6.7, SCR Doc. 15/52). These indices were scaled to true biomass by individual catchability parameters, q_{j} , and lognormal observation errors were applied. Total reported catch in ICES Div. I and II since 1970 was used as yield data (Fig. 6.2, SCR Doc. 15/52). The fishery being without major discarding problems or variable misreporting, reported catches were entered into the model as error-free.

Absolute biomass estimates had relatively high variances. For management purposes, it was therefore desirable to work with biomass on a relative scale in order to cancel out the uncertainty of the "catchability" parameters (the parameters that scale absolute stock size). Biomass, *B*, was thus measured relative to the biomass that would yield Maximum Sustainable Yield, B_{msy} . The estimated fishing mortality, *F*, refers to the removal of biomass by fishing and is scaled to the fishing mortality at MSY, F_{msy} . The state equation describing stock dynamics took the form:

$$P_{t+1} = \left(P_t - \frac{C_t}{B_{MSY}} + \frac{2MSY P_t}{B_{MSY}} \left(1 - \frac{P_t}{2}\right)\right) \cdot \exp(v_t)$$

where P_t is the stock biomass relative to biomass at MSY ($P_t = B_t/B_{MSY}$) in year t. This frames the range of stock biomass on a relative scale where $B_{MSY} = 1$ and the carrying capacity (K) equals 2. The 'process errors', v, are normally, independently and identically distributed with mean 0 and variance σ_p^2 .

The observation equations had lognormal errors, ω , κ , η and ε , for the series of standardised CPUE (*CPUE*_t), Norwegian shrimp survey (*survR*_t), The Russian shrimp survey (*survR*_t) and joint ecosystem survey (*survE*_t) respectively giving:

321

$$CPUE_{t} = q_{C}B_{MSY}P_{t}\exp(\omega_{t}), \ survR_{t} = q_{R}B_{MSY}P_{t}\exp(\kappa_{t}), \ survRu_{t} = q_{Ru}B_{MSY}P_{t}\exp(\eta_{t}), \ survE_{t} = q_{E}B_{MSY}P_{t}\exp(\varepsilon_{t})$$

The observation error terms, ω , κ , η and ε are treated as normally, independently and identically distributed with mean 0 and variances (observation error) σ_c^2 , σ_R^2 , σ_{Ru}^2 and σ_{ε}^2 respectively. Summaries of the estimated posterior probability distributions of selected parameters are shown in Table 6.2. Values are similar to the ones estimated in previous assessments.

Table 6.2. Shrimp in ICES SA I and II: Summary of parameter estimates: mean, standard deviation (sd) and quartiles of the posterior distributions of selected parameters (symbols are as in the text; r = intrinsic growth rate, $P_0 =$ the 'initial" stock biomass in 1969).

	Mean	sd	25 %	Median	75 %
MSY (ktons), maximum sustainable yield	265	197	120	213	357
K (ktons), carying capacity	3522	1869	2093	3115	4549
r, intrinsic growth rate	0.31	0.16	0.19	0.30	0.42

Reference points. Four reference points are considered: F_{msy} , $B_{trigger}$, F_{lim} and B_{lim} . In the present assessment, F_{msy} is estimated directly as is the probability of exceeding reference points. "Buffer" reference points are obsolete due to the available risk analyses. B_{lim} is set at 30% B_{msy} (NIPAG, 2006), $B_{trigger}$ at 50% B_{msy} and F_{lim} at 1.7 F_{msy} (NIPAG, 2010).

	Туре	Value	Technical basis
	B _{trigger}	$0.5B_{MSY}$	Approximately corresponding to 10^{th} percentile of the B_{MSY}
MSY approach			estimate
	F _{MSY}		Resulting from the production model.
Precautionary B _{lim} 0.3B _{MSY} The B where production is reduced to 50% MSY		The B where production is reduced to 50% MSY	
approach	F_{lim}	$1.7F_{MSY}$	the F that drives the stock to B _{lim}

d) Assessment Results

The results of this year's model run are similar to those of the previous years (model introduced in 2006). The conclusions drawn from the model have been found on investigation to be insensitive to the setting of the priors for initial stock biomass and carrying capacity (SCR Doc. 06/64 and 07/76).

Stock size and fishing mortality. A steep decline in stock biomass in the mid-1980s was noted following some years with high catches and the median relative biomass dropped nearly to 1 (Fig. 6.10, upper). Since the late 1980s, however, the stock has varied with a slightly increasing trend. The median 2014-15 values are above B_{msy} . The estimated risk of stock biomass being below $B_{trigger}$ in 2015 is less than 5% (Table 6.3). The median

estimate of fishing mortality has remained below F_{msy} throughout the history of the fishery (Fig. 6.10 lower). In 2015, there is a less than 5% risk of the *F* being above F_{msy} (Table 6.3).

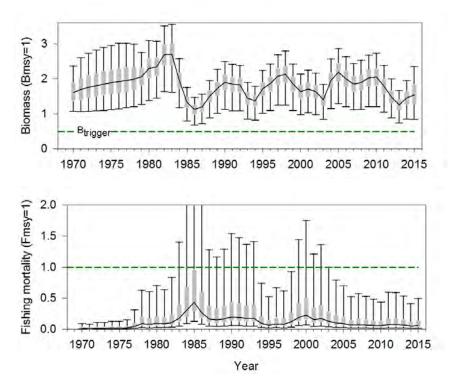

Fig. 6.10. Shrimp in ICES SA I and II: estimated relative biomass (B/B_{msy}) and fishing mortality (F/F_{msy}) for 1970–2015. Boxes represent inter-quartile ranges and the solid black line in the middle of each box is the median; the arms of each box cover the central 90% of the distribution. The broken lines are the $B_{trigger}$ and F_{msy} references respectively.

 Table 6.3.
 Shrimp in ICES SA I and II: stock status for 2014 and predicted to the end of 2015.

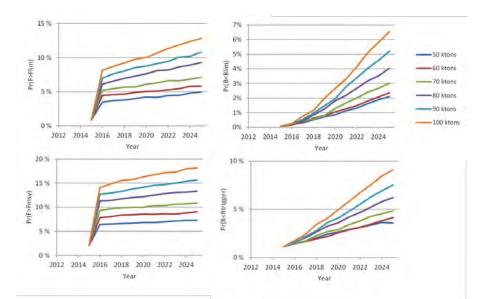

*Predicted catch = 20 ktons

Predictions. Assuming a catch of 20 kt for 2015, catch options up to 70 kt for 2016 have low risks of exceeding F_{msy} (<10%), F_{lim} (<4.9%), and of going below $B_{trigger}$ (<5%) in 2016 (Table 6.4) and all are likely to result in stock increase.

Table 6.4. Shrimp in ICES SA I and II: Predictions of risk and stock status in 2016 associated with six optional catch levels for 2016.

	Catch option 2016 (ktons)							
	50	60	70	80	90	100		
Risk of falling below <i>B</i> _{lim}	0.2 %	0.2 %	0.2 %	0.3 %	0.2 %	0.3 %		
Risk of falling below $B_{trigger}$	1.4 %	1.4 %	1.5 %	1.6 %	1.5 %	1.7 % 14.1		
Risk of exceeding F_{MSY}	6.4 %	7.8 %	9.3 %	11.3 %	12.7 %	%		
Risk of exceeding F _{lim}	3.5 %	4.4 %	4.9 %	6.1 %	7.0 %	8.1 %		
Stock size (B/Bmsy), median	1.59	1.59	1.57	1.57	1.57	1.55		
Fishing mortality (F/Fmsy),	0.15	0.18	0.21	0.23	0.27	0.30		
Productivity (% of MSY)	65 %	66 %	67 %	68 %	68 %	69 %		

The risks associated with ten-year projections of stock development assuming annual catch of 50 000 to 100 000 t were investigated (Fig. 6.11). For all options the risk of the stock falling below $B_{trigger}$ in the longer term (10 years) is less than 10%. Catch options up to 60 000 t, have a low risk (<10%) of exceeding F_{MSY} after 10 years. Taking up to 90 000 t/yr will increase the risk of going above F_{msy} by the end of the ten-year projection to around 15%.

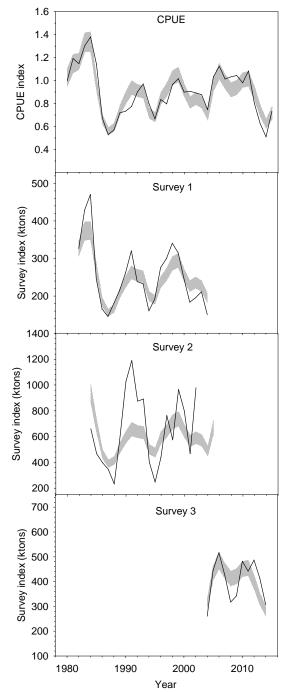

324

Fig. 6.11. Shrimp in ICES SA I and II: Projections of estimated risk of going below $B_{trigger}$ and B_{lim} , and of exceeding F_{msy} and F_{lim} , given different catch options.

Additional considerations

Model performance. The model was able to produce good simulations of the observed data (Fig. 6.12). The differences between observed values of biomass indices and the corresponding values predicted by the model were checked numerically. They were found not to include excessively large deviation.

325

Fig. 6.12. Shrimp in ICES SA I and II: Observed (solid line) and estimated (shaded) series of the included biomass indices: the standardized catch-per-unit-effort (CPUE), the 1982–2004 shrimp survey (survey 1), a Russian survey index discontinued in 2005 (Survey 2) and the Joint Norwegian-Russian Ecosystem Survey (survey 3) since 2004. Grey shaded areas are the inter-quartile ranges of their posteriors.

Predation. Both stock development and the rate at which changes might take place can be affected by changes in predation, in particular by cod, which has been documented as capable of consuming large amounts of shrimp. Continuing investigations to include cod predation as an explicit effect in the assessment model have so far not been successful; it has not been possible to establish a relationship between the density of cod and

the stock dynamics of shrimp. The cod stock in the Barents Sea has increased considerably within the last ten years. If predation on shrimp were to increase rapidly beyond the range previously experienced, the shrimp stock might decrease in size more than the model results have indicated as likely.

Recruitment, and reaction time of the assessment model. The model used is best at projecting trends in stock development but estimates, and uses, long-term averages of stock dynamic parameters. Large and/or sudden changes in recruitment or mortality may therefore be underestimated in model predictions. However such changes have not been observed in the recent period.

Rebuilding potential. At 30% B_{msy} (B_{lim}) production is reduced to 50% of its maximum. With an 80% confidence interval on *r* (the intrinsic rate of increase) ranging from 0.11 to 0.53 per year, it would take 4-14 years to rebuild the stock from B_{lim} to B_{msy} without a fishery.

e) Summary

Mortality. Fishing mortality is likely to remained below F_{msy} throughout the history of the fishery. In 2015 there is a less than 5% risk of the *F* being above F_{msy} with a projected catch at 20 000 t.

Biomass. Stock biomass has been above $B_{trigger}$ throughout the history of the fishery. The risk that the biomass at the end of 2015 is below $B_{trigger}$ is less than 5%

Recruitment. Recruitment indices have varied without trend in 2004 – 2013; no data from 2014.

State of the Stock. The stock has remained around $1.4B_{msy}$ since 2012, with a low risk of being below $B_{trigger}$. The risks of fishing mortality being above F_{msy} at the end of 2015 is less than 5%.

Yield. Catch options up to 70 000 t/yr, have a risk below 10% of exceeding F_{msy} and below 4.9% of exceeding F_{lim} in 2016. At a higher risk larger yields may be achieved. E.g. catches of more than 200 kt can be taken without exceeding the median estimate of F_{msy} .

Special Comment. In recent years the distribution of the stock has changed, and some of the traditional fishing grounds are now less attractive to the fishery. Access to certain other fishing grounds is restricted by closures to prevent bycatch, and by regulations requiring vessels to sail long distances to specified entry and exit points of the Russian EEZ.

f) Review of Recommendations from 2014

For the shrimp stock in Barents Sea and Svalbard (ICES Div. I and II), NIPAG **recommended** that *the technical basis for the assessment in various SCR Docs be collated into a single technical stock annex*.

STATUS: There has been no progress on this recommendation

NIPAG reiterated its **recommendations** from 2010 that, for the shrimp stock in Barents Sea and Svalbard (ICES Div. I and II):

• Demographic information (length, sex and stage etc.) be collected also from the Norwegian part of **the Joint** Norwegian – Russian Ecosystem Survey.

STATUS: There has been no progress on this recommendation

• Collaborative efforts should be made to standardize a means of predicting recruitment to the fishable stock.

STATUS: There has been no progress on this recommendation

• Work to include explicit information on recruitment in the assessment model should be continued.

STATUS: There has been no progress on this recommendation.

g) Research Recommendations

There were no research recommendations.

40. Northern shrimp in Fladen Ground (ICES Division IVa)

From the 1960s up to around 2000 a significant shrimp fishery exploited the shrimp stock on the Fladen Ground in the northern North Sea. A short description of the fishery is given, as a shrimp fishery could be resumed in this area in the future. The landings from the Fladen Ground have been recorded since 1970 (SCR Doc. 09/69). Total reported landings have fluctuated between zero since 2006 to above 8 000 t (Figure 7.1). The Danish fleet accounts for the majority of these landings, with the Scottish fleet landing a minor portion. The fishery took place mainly during the first half of the year, with the highest activity in the second quarter. Since 2006 no landings have been recorded from this stock.

Since 1998 landings have decreased steadily and since 2004 the Fladen Ground fishery has been virtually non-existent with total recorded landings being less than 25 t. Interview information from the fishing industry obtained in 2004 gives the explanation that this decline is caused by low shrimp abundance, low prices on the small shrimp which are characteristic of the Fladen Ground, and high fuel prices. This stock has not been surveyed for several years, and the decline in this fishery may reflect a decline in the stock.

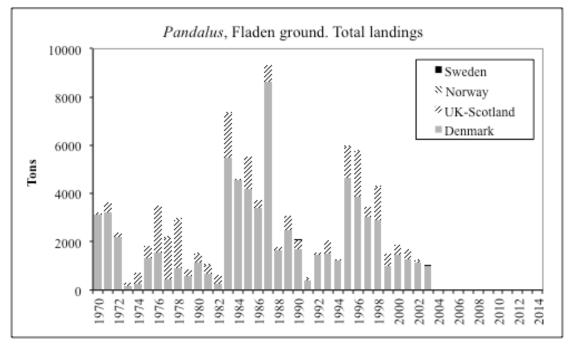

Fig. 7.1. Northern shrimp in Fladen Ground: Landings

III. OTHER BUSINESS

1. FIRMS Classification for NAFO Shrimp Stocks

The table as agreed in June was updated with the agreed classifications for the Northern shrimp stocks assessed this year.

Stock Size	Fishing Mortality			
(incl. structure)	None-Low	Moderate	High	Unknown
Virgin-Large	3LNO Yellowtail flounder			
Intermediate	3M Redfish ³ 3LN Redfish 3NO Witch flounder	SA0+1 Northern shrimp ¹ DS Northern shrimp ¹ 0&1A Offsh. & 1B– 1F Greenland halibut	3M Cod	Greenland halibut in Uummannaq ² Greenland halibut in Upernavik ² Greenland halibut in Disko Bay ² SA1 American Plaice SA1 Spotted Wolffish
Small	SA3+4 Northern shortfin squid 3NOPs White hake			3LNOPs Thorny skate SA2+3KLMNO Greenland halibut
Depleted	3M American plaice 3LNO American plaice 2J3KL Witch flounder 3NO Cod 3M Northern shrimp ^{1,3} 3LNO Northern shrimp ¹			SA1 Redfish SA0+1 Roundnose grenadier SA1 Atlantic Wolffish
Unknown	SA2+3 Roughhead grenadier 3NO Capelin 30 Redfish			SA2+3 Roundnose grenadier

¹ Shrimp will be re-assessed in September 2015

² Assessed as Greenland halibut in Div. 1A inshore

³ Fishing mortality may not be the main driver of biomass for Div. 3M Shrimp and Redfish

41. Future Meetings

The next meeting of NIPAG will be held at ICES Headquarters, Copenhagen, during 7 – 14 September, 2016. The chairs stressed the importance of the administrative support provided by the NAFO Secretariat staff in helping this meeting achieve its objectives, and requested the SC Coordinator and SIA attend future meetings.

42. Long-term management strategy for Northern shrimp (*Pandalus borealis*) in Skagerrak and the Norwegian Deep.

In addressing the request from Norway to ICES on development of a long-term management plan for Northern shrimp in the Skagerrak and Norwegian Deep (Annex III), the group responded:

The accepted approach for evaluating management plans is to evaluate one or more management strategies consistent with the plan using the approach of Management Strategy Evaluation (MSE; Punt et al. 2014).

A full MSE to evaluate the proposed long-term management strategy is a large undertaking that will likely take up to two years to complete. It requires the availability of one or more quantitative fisheries scientists for all or part of that time.

MSE is characterized by applying the management strategy to the perceived population as seen through the lens of the stock assessment in a computer simulation. The stock assessment is based on data generated with error from the simulated true population and fishery.

It is essential that model for the simulated population and fishery (called the operating model) captures the main sources of uncertainty, such as in stock-recruitment, natural mortality, body growth, discarding etc.

Typically more than one operating model is considered, based on alternative assumptions regarding the population and fishery that are equally plausible given the available data.

In the simulation, the assessment is typically applied at each time step to generate the perceived state of the stock. The management strategy is then applied to this perceived state in the form of a feedback harvest control rule. This can be complicated to program and take time to run on the computer. ICES has developed a "short-cut" approach to MSE (ICES 2013a) in which, rather than applying the stock assessment in each time step of the simulation, the assessment is approximated by generating observations directly, with error, from the true simulated population. This short-cut method may be appropriate in some cases but is less desirable than a full MSE and conclusions may not be robust to the assessment errors. A full MSE is therefore recommended.

There are two models currently under consideration by ICES for providing advice on the SKND Pandalus stock, as identified by the 2013 ICES Inter-benchmark process (ICES 2013b). The model applied in the 2013-15 assessments had been a surplus production model (SPM; Hvingel 2012, 2014). The other model is a length-based model (LBM) described in Nielsen et al. 2012, 2015). The LBM was preferred by the Inter-benchmark (ICES 2013b) as the assessment model but there have been some problems in getting the LBM fully functional. This was achieved in 2015, however there are still some concerns based on the diagnostics and model estimates that require further consideration. Consequently scientific advice in 2015 was again based on the SPM.

Neither assessment model had previously been used as a basis for MSE and considerable work may be required before an MSE can be carried out based on either assessment model. If the more complex model, LBM, is considered as a basis for the operating model, it could be used to generate data within an MSE to which the SPM, as an assessment model, could be applied. The reverse is not the case because SPM cannot generate length frequency data.

Workplan

- 1. Complete remaining work on the LBM to answer issues raised in the most recent NIPAG meeting.
- 2. Determine what work would be required to use both/either the LBM and/or SPM as the basis for MSE.
- 3. Hire early to mid-career quantitative scientist to carry out the work required for MSE using one or both models to be undertaken under supervision of one or more senior researchers proficient in the biology, fishery and assessment models for the SKND *Pandalus* stocks, as well as a good understanding of MSE.
- 4. Conduct an initial meeting between scientists and managers/decision makers to clarify the approach to be undertaken, clarify the management objectives, quantify these objectives into performance statistics and agree on acceptable outcomes with regard to imperative and trade-off performance statistics that meet the objectives (see for example Miller and Shelton 2010).
- 5. Consult *Pandalus* experts and modelers to agree on major sources of uncertainty to include and the number and characteristics of the operating models required.
- 6. Carry out programming required to set up the MSE. Do deterministic runs to ensure that the software is working correctly.
- 7. Carry out preliminary stochastic runs and compute performance statistics.

- 9. Carry out final runs of the MSE, prepare results and write a full report.
- 10.Constitute an expert independent peer review of methods and results.
- 11. Carry out any final revisions to MSE based on the peer review.
- 12. ICES presents report and results to Norway, along with peer review report.

43. Chairs of Future Meetings

NIPAG considered the succession of the chairmanship and elected Guldborg Soevik as its chair from the ICES community. Joel Vigneau was elected as chair of NAFO's Standing Committee on Fisheries Science in June, and as such, will become the other NIPAG co-chair. The proposed ICES terms of reference for the group are presented in Annex IV.

IV. ADJOURNMENT

The NIPAG meeting was adjourned at 1500 hours on 16 September 2015. The Co-Chairs thanked all participants, especially the designated experts and stock coordinators, for their hard work. The Co-Chairs thanked the NAFO and ICES Secretariats for all of their logistical support. Special thanks were given the to Department of Fisheries and Oceans for their hospitality during this meeting.

REPORT OF SCIENTIFIC COUNCIL MEETING

21-25 September 2015

Chair: Don Stansbury

Rapporteur: Neil Campbell

I. PLENARY SESSIONS

The Scientific Council met at the Westin Nova Scotian, Halifax, Nova Scotia, Canada, during 21-25 September 2015, to consider the various matters in its agenda. Representatives attended from Canada, European Union (France, Portugal, Spain and the United Kingdom), France (with respect to St. Pierre et Miquelon), Norway, the Russian Federation and the United States of America. The Scientific Council Coordinator was in attendance.

The Executive Committee met prior to the opening session of the Council to discuss the provisional agenda and plan of work.

The opening session of the Council was called to order at 0930 hours on 21 September 2015.

The Chair welcomed participants to the 37th Annual Meeting and thanked the NAFO Secretariat for hosting this event.

The provisional agenda was adopted with minor additions. The Council appointed Neil Campbell, the Scientific Council Coordinator, as rapporteur. The Chair welcomed the Ecology Action Centre and FAO as observers to this meeting.

The Council and its Standing Committees met through 21-25 September 2015 to address various items in its agenda. The Council considered and adopted the reports of the STACFIS and STACREC Standing Committees on 25 September 2015. The final session was called to order at 0900 hours on 25 September 2015. The Scientific Council then considered and adopted its report of this meeting. The meeting was adjourned at 1100 hours on 25 September 2015.

The Reports of the Standing Committees as adopted by the Council are appended as follows: Appendix I - Report of Standing Committee on Research Coordination (STACREC), and Appendix II - Report of Standing Committee on Fisheries Science (STACFIS).

The Agenda, List of Research (SCR) and Summary (SCS) Documents, and the List of Representatives, Advisers and Experts, are given in Appendices III, IV, and VI, respectively.

II. REVIEW OF SCIENTIFIC COUNCIL RECOMMENDATIONS

There were no recommendations arising from the 2013 or 2014 Scientific Council Meetings.

III. RESEARCH COORDINATION

The Council adopted the Report of the Standing Committee on Research Coordination (STACREC) as presented by the Chair, Kathy Sosebee. The full report of STACREC is at Appendix I.

IV. FISHERIES SCIENCE

The Council adopted the Report of the Standing Committee on Fisheries Science (STACFIS) as presented by the Chair, Brian Healey. The full report of STACFIS is at Appendix II.

V. REQUESTS FROM THE FISHERIES COMMISSION

1. Requests deferred from the June Meeting

a) Capelin in Div. 3NO

Scientific Council responded:

333

Capelin in Div. 3NO

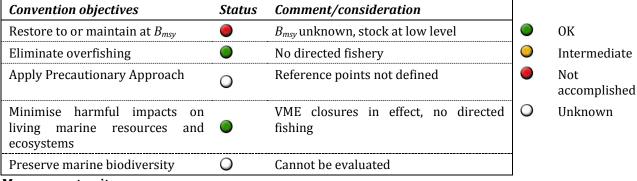

Recommendation for 2016-2018

No directed fishery.

Management objectives

No explicit management plan or management objectives defined by Fisheries Commission. General convention objectives (GC Doc. 08-03) are applied. Advice is based on qualitative evaluation of biomass indices in relation to historic levels.

334

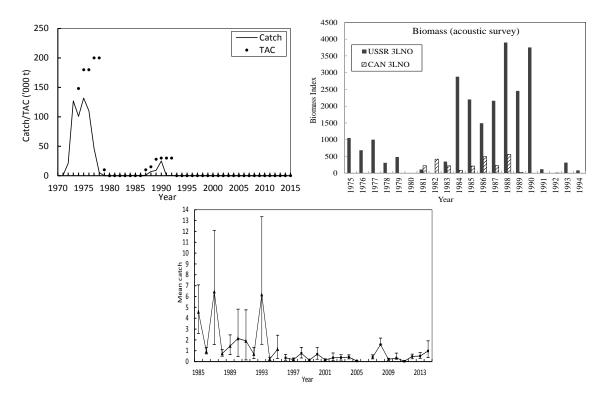

Management unit

The capelin stock is distributed in Div. 3NO, mainly on the Grand Bank.

Stock status

Acoustic surveys series terminated in 1994 indicated a stock at a low level. Although biomass indices have increased in recent years, bottom trawl surveys are not considered a satisfactory basis for a stock assessment of a pelagic species.

Reference points

Not defined.

Projections

Quantitative assessment of risk at various catch options is not possible for this stock at this time.

Assessment

Assessment was based on evaluation of trends in acoustic survey data (1975 – 1994) and bottom trawl surveys (1995 – 2014). Bottom-trawling is not a satisfactory basis for a stock assessment of a pelagic species. At best the assessment is only indicative of major changes in abundance.

335

Next full assessment is scheduled for 2018. Unless an acoustic survey is available, Scientific Council will be unable to produce more specific advice.

Human impact

Low fishery related mortality due to moratorium and low bycatch in other fisheries. Other sources (e.g. pollution, shipping, oil industry) are considered minor.

Biological and Environmental Interactions

Changes in growth, maturity and recruitment are linked to temperature on the Grand Banks. Recent changes in temperature (STACFEN 2015) may provide more favorable conditions for capelin. Predatory groundfish in Div. 3NO have increased slightly in recent years, and may cause increased natural mortality through predation.

Fishery

Capelin was caught in a directed trawl fishery. There is low bycatch in other trawl fisheries. The fishery is regulated by quota and has been under moratorium since 1995, and there were no reported catches between 1994 and 2013. Recent catch estimates and TACs (t) are as follows:

	2006	2007	2008	2009	2010	2011	2012	2013	2014	2015
TAC	ndf									
STATLANT 21	0	0	0	0	0	0	0	0	1	

ndf - no directed fishery

Effects of the fishery on the ecosystem

No fishery.

Special comments

Bottom-trawling is not a satisfactory basis for a stock assessment of a pelagic species and survey results are indicative only. Investigations to evaluate the status of capelin stock should utilize trawl acoustic surveys to allow comparison with historical time series.

Source of Information

SCR Doc. 15/27

b) Advice on Yellowtail flounder for 2018

Scientific Council responded:

Yellowtail Flounder in Divisions 3LNO

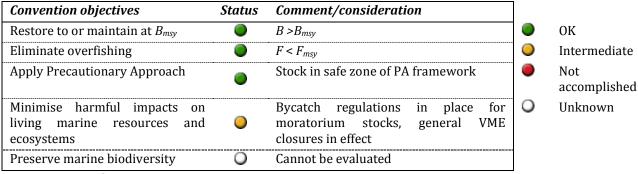

Advice September 2015

Recommendation for 2016, 2017 and 2018

Based on recent catch levels, fishing mortality up to $85\% F_{msy}$ corresponding to a catch of 26 300 t in 2016, 23 600 t in 2017 and 22 000 t in 2018 has low risk (5%) of exceeding F_{lim} , and is projected to maintain the stock well above B_{msy} .

Management objectives

No explicit management plan or management objectives are defined by Fisheries Commission. General convention objectives (NAFO/GC Doc. 08/3) are applied. Advice is provided in the context of the Precautionary Approach Framework (NAFO/FC 04/18).

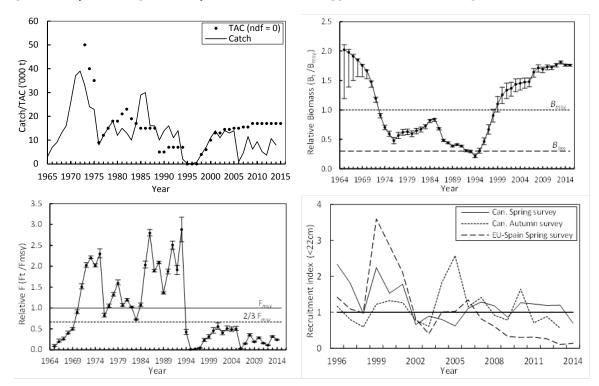

Management unit

The stock occurs in Divs. 3LNO, mainly concentrated on the southern Grand Bank and is recruited from the Southeast Shoal area nursery ground.

Stock status

The stock size has steadily increased since 1994 and is now well above B_{msy} . There is very low risk of the stock being below B_{msy} or F being above F_{msy} . Recent recruitment appears lower than average.

Reference points

Blim 30% Bmsy

*F*_{lim} *F*_{msy} (STACFIS 2004 p 133).

Projections

Projections were conducted assuming two levels of catch in 2015: TAC level (17 000t) and the average of the 2007-2014 catch (7 400 t) followed by constant fishing mortality from 2016-2018 at 2/3 F_{msy} , 75% F_{msy} , and 85% F_{msy} . Although yields are projected to decline in the medium term at both levels of catch in 2015, at the end of the projection period, the risk of biomass being below B_{msy} is less than 1% in all cases. The probability of biomass increasing in the projection period (P($B_{2018}>B_{2014}$)) is <1%. The stock is well above B_{msy} and the projected levels of F result in catches higher than the estimated surplus production which will result in a decline in biomass toward B_{msy} .

Assessment

A surplus production model was used (STACFIS 2015). The results were consistent with the previous assessment and are considered to be reliable. Input data comes from research surveys and the fishery (STACFIS 2015) and is considered good quality. Next assessment: 2017.

Human impact

Mainly fishery related mortality has been documented. Other sources (e.g. pollution, shipping, oil industry) are undocumented.

Biology and Environmental interactions

As stock size increased from the low level in the mid-90s, the stock expanded northward and continues to occupy this wider distribution. This expansion of the stock coincided with warmer temperatures; temperatures continue to warm, and will likely not limit the stock distribution in the near future.

Despite the increase in stock size observed since the mid-90s, the average length at which 50% of fish are mature has been lower for both males and females in the recent period. There also seems to have been a slight downward trend in weight at length since 1996. The cause of these changes is unknown.

Fishery

Yellowtail flounder is caught in a directed trawl fishery and as by-catch in other trawl fisheries. The fishery is regulated by quota and minimum size restrictions. Catches in recent years have been low due to industry-related factors. American plaice and cod are taken as by-catch in the yellowtail fishery. There is a 15% by-catch restriction on American plaice and a 4% limit on cod.

	2006	2007	2008	2009	2010	2011	2012	2013	2014	2015
TAC1	15.0	15.5	15.5	17	17	17	17	17	17	17
STATLANT 21	0.6	4.4	11.3	5.8	9.3	5.2	3.2	10.5	8.0	
STACFIS	0.9	4.6	11.4	6.2	9.4	5.2	3.1	10.7	8.0	

Recent catch estimates and TACs ('000 t) are as follows:

SC recommended any TAC up to 85% Fmsy in 2009-2015. **Effects of the fishery on the ecosystem**

Fishing intensity on yellowtail flounder has impacts on Divs. 3NO cod and Divs. 3LNO American plaice through by-catch. General impacts of fishing gears on the ecosystem should also be considered.

Special comments

Catch of yellowtail flounder has been below TAC in recent years. If catches increase, fishing mortality on Divs. 3NO cod and Divs. 3LNO American plaice will also increase.

Sources of information

2. Requests received from the Fisheries Commission during the annual meeting

The following requests were received during the current meeting. Scientific Council noted that these responses are only for the clarification of the advice and do not in any way alter or change the advice published in the previous reports of the Scientific Council.

341

a) Cod in Division 3M

Fisheries Commission requested:

8. Regarding the Div. 3M cod advisory sheet, in the projection table for 3M cod the estimated risk of F being larger than Flim in scenario no. 2 (3/4 Flim) is estimated at less than 1%. It seems, however, that by looking at the overlaps of the 90% confidence limits of the catches associated with scenario #1 and scenario #2 that this risk ought to be higher (in the order of 5 to 20%). Is this correct?

Scientific Council responded:

The council agreed the risk of $F > F_{lim}$ tabulated is underestimated in this case (scenario #2), but the magnitude is unknown. The Council noted this had no bearing on the projected values of yield, biomass and SSB. The Council could not come to a consensus on a better way of expressing risk and uncertainty at this time. Scientific Council will work intersessionally to resolve this issue by June 2016.

9. Noting that the NAFO PA framework specifies an exploitation boundary with a low risk (~20%) of exceeding Flim and that FC requests the SC to provide advice in accordance with the PA, why is SC promoting advice that implies a risk of 50% of exceeding Flim?

Scientific Council responded:

The TAC recommendation is that the catch be less than that generated by the corresponding F_{lim} . Yields less than those corresponding to fishing at F_{lim} would result in lower risks of exceeding F_{lim} , however the tolerance of such risk is a decision for managers. Unfortunately none of the scenarios considered provided a risk in the order of 20%. Moreover in all scenarios there is a high probability of biomass growth during the projection period.

10. Fishing at Flim in 2016-2017 would imply a 55% reduction of fishing mortality from 2014 and the exploitation would be kept 18% below the estimated natural mortality. At this level, it is expected with a high probability (95%) that SSB will continue to increase from 2014 to 2018. Also, fishing at a higher rate (e.g. between Flim and ¾ F2012-2014) will still imply a high probability of biomass increase and a risk below 1% that biomass would fall below Blim by 2018.

Is there a scientific reason to justify the need for a TAC reduction in 2016 followed by an increase in 2017? What are the biological risks for the stock of reducing the TAC variation from year to year and stabilizing the TAC at the mean of the advised TACs for 2016 and 2017?

Scientific Council responded:

Advice was given in terms of F_{lim} projections and these were the resulting yields. Scientific Council sees no significant changes in the projected SSB when averaging over the projected yields. By increasing the TAC in 2016 from 12 425 to 13 931 and reducing the 2017 TAC from 15 436 to 13 931 the fishing mortality will increase above F_{lim} (F_{2016} = 0.15) in 2016 and be below F_{lim} in 2017 (F_{2017} = 0.12).

11. The SC has stated a decrease in the mean size of the catches of Div. 3M cod and has concluded that the implementation of sorting-grids in Div. 3M cod fishery would reduce catches of small and immature individuals of cod. Having these conclusions in mind, is the Scientific Council in a position at this meeting to formulate a proposal for selectivity experiments with sorting grids in the Flemish Cap area for 2016, i.e. outlining the temporal and spatial coverage of the area, number of vessels required, gear needed for the experiments, etc. Scientific Council responded:

Scientific Council is not in a position at this meeting to develop a research plan for investigating selectivity in Div. 3M Cod. SC would encourage any Contracting Party to conduct such selectivity experiments and would welcome the opportunity to review results.

b) Redfish in Div. 3M

Fisheries Commission requested:

1. What would be the average 2016-2017 TAC for 3M redfish, keeping for beaked redfish the fishing mortality at 2013-2014 Fstatus quo and assuming that natural mortality on 2015-2017 will be at the same estimated average level of the past couple of years (2013-2014)?

Scientific Council responded:

The average projected 2016-2017 catch for Div. 3M beaked redfish, is presented in the STACFIS Report. The average 2013-14 proportion of beaked redfish in the Div. 3M redfish catch is estimated to be 64%. Scientific Council reiterates its concern, "Given the uncertainty about the actual level of current natural mortality (see STACFIS, 2015) and its impact on short term model projections, Scientific Council decided not to use model predictions as a basis for the recommendation."

The SC also reiterates its advice that "Recent decline in proportion of S. mentella and S. fasciatus allows a marginal increase in TAC in 2016-17 to 7000t, without changing the exploitation rate on these species and having the stock remain at a relatively high level".

c) Splendid alfonsino (*Beryx splendens*)

Fisheries Commission requested:

1. There are three known banks on which the fishery for Alfonsino has been conducted (Kükenthal Peak, C-3 and Milne-Edwards). The SC is requested to clarify if there has been any research into the Alfonsino stock carried out on the C-3 and Milne-Edwards banks and to provide any intermediate results of such research.

Scientific Council is not aware of research on C-3 and Milne Edwards peaks, beyond that presented in SCR Doc. 15/06, and reviewed in the June meeting.

2. According to the advice on the Alfonsino stock presented, three mean catch values (2, 5 and 10- year intervals) have been calculated. The SC is requested to elaborate if any one of these values is more appropriate to be used as a basis for establishing the TAC and has any advantages over the others.

Scientific Council considered that the 10-year average is too long to reflect current productivity. There was no strong justification for choosing one of the remaining averaging periods (2009-2014 or 2012-2014) over the other – stock status is unknown, as is the sustainability of any of these options.

3. The SC is requested to provide the catch statistics by the Contracting Parties that conducted fishery for Alfonsino in the areas and time periods in question.

The following table was extracted from the STATLANT 21 database and provided by the Secretariat.

Year	Country	Division	Species Name	ASFIS Code	Catch (t)
2014	Spain	6G	Alfonsinos (ns)	ALF	118
2013	Spain	6G	Alfonsinos (ns)	ALF	112
2012	Spain	6G	Alfonsinos (ns)	ALF	298
2010	Spain	6G	Alfonsinos (ns)	ALF	53
2006	Spain	6G	Alfonsinos (ns)	ALF	69
2005	Spain	6G	Alfonsinos (ns)	ALF	577

VI. MEETING REPORTS

1. Joint Fisheries Commission – Scientific Council – WG Ecosystem Approach Framework to Fisheries Management

This joint working group met during 15 – 17 July 2015, and was chaired by Andrew Kenny (EU-United Kingdom) (FC-SC Doc 15/03). The Scientific Council was advised of progress in this group by the Chair in their presentation of the report to the joint session of Fisheries Commission and Scientific Council.

2. Joint Fisheries Commission-Scientific Council - WG on Risk-based Management Strategies

This joint working group met during 22– 24 April 2015, and was co-chaired by Carsten Hvingel (Norway) and Kevin Anderson (Canada) (FC-SC Doc 15/02). The Scientific Council was advised of progress in this group by Dr. Hvingel in his presentation of the report to the joint session of Fisheries Commission and Scientific Council. Responses to the group are detailed under Other Business.

3. Joint Fisheries Commission-Scientific Council - WG on Catch Reporting

This joint working group met during 20 – 21 April 2015, and was co-chaired by SC Chair Don Stansbury (Canada) (FC-SC Doc. 15/01). The Scientific Council was advised of progress in this group by the Chair in his presentation of the report to the joint session of Fisheries Commission and Scientific Council.

4. Fisheries Commission – WG on Bycatch, Discards and Selectivity

This Fisheries Commission Working Group met at the NAFO Secretariat 13 – 14 July 2015, and was chaired by FC Chair Sylvie Lapointe (Canada). The Scientific Council was advised of progress in this group by the Chair in her presentation of the report to the joint session of Scientific Council and Fisheries Commission.

VII. SPECIAL SESSIONS

The most recent NAFO symposium, *The Role of Marine Mammals in the Ecosystem in the 21st Century,* was held in 2008. As we have discussed at previous Scientific Council meetings, it is the symposia that have led to increased numbers of publications in the JNAFS. The following suggestions of topics were received at the June 2015 meeting, and forwarded to the September meeting for further consideration.

- 1. Regime shifts in stock productivity: environmental or anthropogenic?
- 2. Workshop on stock assessment methods
- 3. Variable population parameters K_i , r_i , M_i
- 4. Otolith data as a tool to track life history changes and population parameters

In general, Scientific Council felt that the workload upcoming in 2016 and 2017 discouraged the possibility of holding a special session at this time.

At the NIPAG meeting in St Johns, the possibility of a joint NAFO-ICES conference on aging techniques for prawns was discussed. This was well received in general, but it was felt that further work was required before we would be in a position to have a symposium discussing results; therefore this was placed on hold for now.

Scientific Council noted the intent to hold a benchmark meeting on assessment of Div. 3M cod in 2017 and agreed the chair would bring this issue up in the presentation of the SC budget to ensure resources are available to support participation.

VIII. REVIEW OF FUTURE MEETING ARRANGEMENTS

1. Scientific Council, 3 – 16 June 2016

Scientific Council agreed that its June meeting will be held on 3 – 16 June 2016, at St Mary's University, Halifax.

2. Scientific Council (in conjunction with NIPAG), 7 - 14 Sep 2016

The next Scientific Council shrimp meeting is scheduled to meet at ICES Headquarters, Copenhagen, Denmark. The agreed dates are 7 – 14 September, 2016.

3. Scientific Council, 19 – 23 September 2016

Scientific Council noted that the Annual meeting will be held 19 – 23 September in Cuba.

4. Scientific Council, 2 – 15 June 2017

Scientific Council agreed that its June meeting will be held on 2 – 15 June 2017, at St Mary's University, Halifax.

Scientific Council noted the overlap in timing between the NAFO Annual Meeting and the ICES Annual Science Conference. This discourages participation of SC members in the Annual Meeting. It was agreed that the SC Chair will discuss this with the incoming GC and FC chairs.

5. NAFO/ICES Joint Groups

a) WG-DEC, February 2016

The next meeting of the ICES–NAFO Working Group on Deepwater Ecosystems is scheduled to take place at ICES Headquarters, Copenhagen, Denmark, during February 2016.

b) NIPAG, 7 – 14 September 2016

This meeting will be held 7 – 14 September 2016, Copenhagen, Denmark.

6. NAFO SC Working Groups

a) WG-ESA, 17 - 26 November, 2015

The Working Group on Ecosystem Science and Assessment will meet at the NAFO Secretariat, Dartmouth, Nova Scotia, Canada, 17 - 26 November, 2015.

IX. OTHER MATTERS

1. Presentation on redfish recruitment

Dr. Alexandra Valentin (DFO, Mont-Joli) was invited by the Scientific Council to make a presentation on redfish recruitment, based on a recent peer-reviewed publication (Valentin, A.E., Power, D., Sévigny, J.-M. 2015. Understanding recruitment patterns of historically strong juvenile year-classes in redfish (*Sebastes* spp): the importance of species identity, population structure, and juvenile migration. Canadian Journal of Fisheries and Aquatic Sciences 72: 774–784).

In this study, genetic analyses (i.e. 13 microsatellite markers) were undertaken on archived otoliths from juveniles representing historically strong year-classes of northwest Atlantic redfish (Sebastes spp.) and on tissue samples from adults of known species and population of origin. The results indicated that the species composition of a year-class is key information for understanding recruitment dynamics, with *S. fasciatus* and *S. mentella* species having distinct population-associated patterns of spatial dispersion. In the Gulf of St. Lawrence-Laurentian Channel area (i.e. Canadian fisheries management zones 'UNIT1' and 'UNIT2'), the last strong year-class which supported the fishery for more than 30 years belonged to *S. mentella*. This year-class carried the same genetic signature as the *S. mentella* adult population in the UNIT1-UNIT2 area, which suggested a local origin of this year-class. It is suggested that the Gulf of St. Lawrence (UNIT1) is the main nursery area for the UNIT1-UNIT2 *S. mentella* population and that juveniles disperse across the whole area as they age. In contrast, four year-classes that appeared abundant at young ages in UNIT1 and UNIT2 research surveys, but contributed only marginally to the adult population and the fishery in those regions, belonged to

S. fasciatus. These four year-classes carried the genetic signature of the adult population distributed along the southern margin of Div. 3Ps in UNIT2 and the slope of the Newfoundland Grand Banks (which includes Div. 3LN and Div. 3O). Ocean currents and spatio-temporal trends in abundance-at-length suggested that the latter adult population uses the Gulf of St. Lawrence as a nursery area, with larvae/early juveniles drifting toward the Gulf of St. Lawrence and older juveniles migrating back (i.e. homing behaviour) to the slope of the Grand Banks (at least to Div. 3O) after about five to six years. In summary, this study illustrated the importance of acknowledging population-associated patterns of spatial dispersion at key life-history stages for understanding redfish recruitment dynamics. By extension, this study suggested that juvenile migration behaviour is a post-settlement process that plays an important role in redfish recruitment dynamics and carries both demographic and evolutionary implications.

345

The discussion among the participants focused on the extent to which the strong year-classes of *S. fasciatus*, which use the Gulf of St. Lawrence as a nursery area, contribute to the recruitment of S. fasciatus in the Div. 3LN + Div. 30 area. Survey data (1991-2013) from Div. 3LN suggest the occurrence of recent good recruitments since 2008, after a period of low productivity that prevailed for more than 15 years. It has also been shown that Div. 30 and Div. 3N have always been composed of a large proportion of small redfish in the 20cm-25cm range without a consistent tracking of juvenile sizes, suggesting younger fish must come from elsewhere. Moreover, these areas are dominated by S. fasciatus. This new research linking S. fasciatus recruitment in Div. 3LN + Div. 3O to the disappearance of historically strong year-classes in the Gulf of St. Lawrence provides a credible mechanism to explain this situation which has puzzled scientists for many years. While the Council noted the importance of this research in regard to the management of redfish, there are still some challenging aspects of redfish biology that require answers before contemplating revisions to current management units. These include, for example, mixing/migration rates, spawning locations and whether there are areas of local retention of larvae/juveniles, and species composition. General discussions also arose on other research that revealed the importance of sea pens (pennatulacean corals) as habitat for redfish larvae along the slope of the Laurentian Channel (Div. 3Ps) and the west slope of the Grand Bank (Div. 30). The extent to which sea pen habitat influences survival of early life stages of redfish is also important research for future management considerations.

Scientific Council expressed its appreciated for this presentation, thanked Dr Valentin for her work and stated its strong support for its continuation.

2. Revision of Annex 1 to Requests from Fisheries Commission

Scientific Council discussed a number of options to assist Fisheries Commission in revising the annex to the FC requests for advice, including providing projections at some percentage risk of exceeding F_{lim} , whether SC should prioritize any particular *F* option, including the risk associated with constant catch over the projection period, and whether all projections should be presented, or should those falling below a specified risk of exceeding F_{lim} be presented.

Feedback on these discussions was provided to Fisheries Commission to assist their deliberations.

3. Discussion on merging STACFEN and WG-ESA

At the June 2015 SC meeting it was agreed the SC, WG-ESA and STACFEN chairs would work intersessionally on the possibilities of merging STACFEN and WGESA. The chair of WG-ESA made a presentation summarizing the issue.

The two groups have complimentary roles, with STACFEN developing policies and procedures for the collection, compilation and dissemination of environmental information from oceanographic investigations; providing reviews of environmental conditions and advice to Scientific Council; and encouraging cooperation among Contracting Parties in scientific research, while WG-ESA addresses terms of reference which include *inter alia*, identification and mapping of sensitive species and habitats in the NAFO area, identifying appropriate ecosystem-based management areas, practical application of ecosystem knowledge to fisheries management, and the long-term monitoring of VME status and functioning. Since its inception in 2008 the work of WGESA has grown in scope and volume, and has become a stable contribution to SC work.

. A A

There are obvious overlaps between the STACFEN directives and the WGESA work (e.g. effects of environment on fish stocks and fisheries) and it was agreed the work of both groups would benefit from closer interactions and collaborations.

A proposal for a route forward was tabled by the chairs, which would involve the creation of a new Standing Committee (NStCo). This group will have directives that will integrate the mandates of both groups. At least initially, it will have two co-chairs that will be renewed every two years. Ideally, renewal of co-chairs should not be done in the same year. The NStCo will have its main meeting in November/December of each year. Detailed environmental summaries would be presented and ecosystem-related FC requests would also be addressed at this meeting at this meeting. A summary of the work done will be presented by the chairs of the NStCo at the SC June meeting including both a synoptic environmental summary as well as relevant progress on ecosystem studies.

The advantages of this approach would be that; it will provide a platform for oceanographers to interact with ecologists to explore interactions beyond environmental summaries, it would enhance the oceanographic expertise in the discussion of ecosystem issues, it will improve the use of time during the SC June meeting by integrating the presentations of current STACFEN and WGESA, and it will update and align the structure of SC with the requirements of the new convention (i.e. ecosystem approach)

Potential drawbacks include the possibility that the synoptic environmental summary may not contain all the information of current summaries; it will potentially reduce the interactions/collaborations between current STACFEN members and members of other Standing Committees, some current STACFEN members may not be able to attend the meeting in November or December, and the duration of this meeting, which typically starts on a Tuesday and ends the following Friday, may need to be extended to two full weeks.

Scientific Council thanked the chairs for their work and had extensive discussions on the issues raised. Feedback was generally positive, but there were some concerns regarding timing of meetings with respect to data availability, the change in requirements for participation between and availability of key personnel in November. Chairs will now present this proposal to WGESA, in November 2015, and STACFEN, in June 2016, before any decisions are made.

4. Scientific Council subgroups

During the June meeting, Scientific Council identified a number of areas which it wanted to work on intersessionally, via dedicated subgroups. These were; the revision of the PA framework, analysis and communication of risk, catches for the Greenland halibut MSE, and on the overlap of fishery surveys and VME closures. To facilitate this work, leads for each group were identified, and tasked with reaching out to SC members to arrange meetings via WebEx, in conjunction with the Secretariat. It was agreed that the SC chair and the chairs of RBMS would identify participants and timelines for the PA revision group, depending on the scheduling of the 2016 RBMS meeting. The identified leads of the remaining groups were Joel Vigneau (risk analysis), Joanne Morgan (GHL catches) and Kathy Sosebee (Survey-VME overlap).

Furthermore, SC was asked to identify a number of participants for the FC-SC Technical Working Group on Catch Reporting. It was felt that participation by the STACREC chair, and DE's for Div. 3M cod, Div. 3LNO American plaice and Greenland halibut would be most beneficial at present.

5. Presentation on the FAO Deep-sea ABNJ Project

Scientific Council received a presentation on the status of the FAO ABNJ – Deep Seas project from the project coordinator, Chris O'Brien (FAO), in which NAFO is a partner. The project aims to achieve efficiency and sustainability in the use of deep-sea living resources and biodiversity conservation in the ABNJ, through systematic application of ecosystem approach. The plan is to divide work into four components:

- 1. Improved application of policy and legal frameworks
- 2. Reducing adverse impacts on VMEs and components of EBSAs
- 3. Improved planning and adaptive management for ABNJ deep-sea fisheries
- 4. Development and testing of a methodology for area-based planning

To date, work has involved coordination of the Global VME database, organizing a review of processes and practices surrounding VME's in RFMO's, development of data collection systems and preparation of a number of species guides and technical papers. Planned for the future are a number of fishery workshops, participation in a research project on deep-sea sponges in the Atlantic and development of tools for biodiversity monitoring by the fishing industry.

347

6. Discussion on benchmark stock assessment meetings

Scientific Council and the outgoing Chair of Fisheries Commission discussed the workload imposed by the proposed Div. 3M cod and redfish benchmarking process. Issues raised included as the prioritization of stocks to undergo this process, disruption to the Div. 3M cod management strategy evaluation, the revision of the PA framework, and the workload generated for the scientists and designated experts. Scientific Council could contribute to the process by making research recommendations in June of relevance to this prioritization. The Council thanked the FC Chair for addressing the meeting on this issue. The Scientific Council Chair will write to the chair of Fisheries Commission to highlight the issues on a formal basis.

7. Awards to outgoing chair.

On behalf of Scientific Council, the Vice-Chair, Kathy Sosebee (USA), thanked the Chair, Don Stansbury (Canada) for his leadership as chair of STACFIS (2001 – 2003), STACREC and SC Vice-Chair (2011 – 2013) and Chair of Scientific Council (2013 – 2015) and presented him with a certificate. Scientific Council wished him all the best for the future.

X. ADOPTION OF REPORTS

1. Committee Reports of STACREC and STACFIS

The Council reviewed and adopted the Reports of the Standing Committees (STACREC and STACFIS).

2. Report of Scientific Council

The Council at its concluding session on 25 September 2015 considered and adopted its own report, with the usual caveat that there will be minor corrections.

XI. ADJOURNMENT

There being no other business, the meeting was adjourned at 1200 hours on 25 September 2015. The Chair thanked the Scientific Council Coordinator for his support during his time with the NAFO Secretariat and wished him the best of luck in his future career. The Chair thanked the NAFO Secretariat for their hospitality in hosting the annual meeting and their usual high standard of logistic support. Finally, the chair thanked the members of Scientific Council for their hard work and wished everyone a safe journey home.

APPENDIX I. REPORT OF STANDING COMMITTEE ON RESEARCH COORDINATION (STACREC)

Chair: Kathy Sosebee

Rapporteur: Neil Campbell

1. Opening

The Committee met at the Westin Hotel, Halifax, Canada, during 24 September 2015, to consider the various matters in its Agenda. Representatives attended from Canada, European Union (France, Portugal, Spain and UK), France (with respect to St. Pierre et Miquelon), Norway, Russian Federation and USA. The Scientific Council Coordinator was in attendance. The Chair opened the meeting and welcomed everyone. Neil Campbell was appointed the Rapporteur.

2. Fisheries Statistics

a) Progress Reports on Secretariat Activities

There were no activities to report on.

b) Review of STATLANT 21

i) Submission of data

The following table updates the situation with the submission of STATLANT. There are still a few outstanding submissions but in general the submission rate is acceptable.

APPENDIX II. REPORT OF STANDING COMMITTEE ON FISHERIES SCIENCE (STACFIS)

349

Chair: Brian Healey

Rapporteur: Neil Campbell

1. Opening

The Committee met at the Westin Hotel, Halifax, Canada, during 24 September 2015, to consider the various matters in its Agenda. Representatives attended from Canada, European Union (France, Portugal, Spain and UK), France (with respect to St. Pierre et Miquelon), Norway, Russian Federation and USA. The Scientific Council Coordinator was in attendance. The Chair opened the meeting and welcomed everyone. Neil Campbell was appointed the Rapporteur.

2. Nomination of Designated Experts

Scientific Council were informed that following the passing of Dave Orr (see SCS Doc. 15/14), Katherine Skanes (Canada) had taken over as the designated expert for Northern Shrimp in Div. 3LNO. There were no other changes proposed.

3. Other Matters

a) Review of SCR and SCS Documents

There were no SCR documents submitted.

b) 2016 invited speaker

At the June 2014 meeting it was decided that funds would be sought to support the attendance of an invited speaker at the 2015 STACFIS meeting. Unfortunately none of the candidates approached were available to attend the meeting. There was still popular support for this initiative, therefore it was concluded that funds would be requested again, and the STACFIS chair and SC coordinator to engage with proposed speakers at the earliest opportunity to ensure their availability.

c) Other Business

i) Communication of risk in advice to managers

It was noted in the requests from FC for clarification of scientific advice that the risks of exceeding F_{lim} for some scenarios presented in the Div. 3M cod assessment were difficult to interpret in light of the overlap in credible intervals of the yields of the various options. This observation lead to an extensive discussion within STACFIS on the methods used to calculate risk, its perception within Scientific Council and the communication such matters to Fisheries Commission.

Three working documents were presented to SC for consideration on the issue of risk estimates associated with projected scenarios. The first detailed the current computation done for the stock, and although there was no computation error, SC acknowledged that the risk proposed did not correspond to the expected one. The remaining two proposed other approaches, which were perceived to be correct by SC, resulting in the two following options:

- The projected parameter and the corresponding reference point both have a known distribution.
- The projected parameter or the corresponding reference point does not have a known distribution.

Falling into one or the other option will depend on the method used, and vary across stock assessments conducted by SC. It was demonstrated that the risk can differ to significant extent from one option to the other. If computing the risk using two distributions is considered more reflective of the reality, the probability of a point value being greater than a distribution will underestimate the risk when the point value is below the median of the distribution and over-estimate when above. The two options are providing the same estimates (50%) only in the case of comparing the parameter to the median of the other. Including all the information (the distribution shapes) when available is a good principle, but given the discrepancy of risk estimates between the two options, the value provided to the managers will have different meaning depending on the option taken. Moreover, the question was raised on the relevance to compute a distribution on an option demanded by the managers (e.g. $3/4 F_{msy}$ is a point value or a variable when evaluating the risk of $3/4 F_{msy}$ being above F_{lim}). These were causes of concern for SC, and it was agreed to propose a plan for

elaborating a standard procedure for all stocks to be included in the NAFO Precautionary Approach Framework (PAF). This initiative is also in line with the setting of a technical subgroup in charge of revising the PAF where a ToR is dedicated to the standard risk computation.

A group led by Joël Vigneau (STACFIS chair) - open to all SC participants - will meet by web conference in the second half of January 2016 to propose a standard procedure and/or good practice to compute the risk in the advice sheet. Joël Vigneau will liaise with the PAF technical subgroup and report this subgroup with the progress made. In preparation of the January meeting, the group will:

- invite key experts to provide advice,
- document how risk is computed (when possible) within the NAFO stock assessments,
- seek guidance from relevant literature and other RFMOs on how such risk estimates are computed,
- propose guidance for application in future assessments

4. Adjournment

The meeting was adjourned at 1200 on 24 September 2015

PART H: MISCELLANEOUS

A – Fisheries Commission and Scientific Council <i>ad hoc</i> Working Group on Catch Reporting, 20-21 April 2015 - Agenda	353

A – FISHERIES COMMISSION AND SCIENTIFIC COUNCIL *AD HOC* WORKING GROUP ON CATCH REPORTING, 20-21 APRIL 2015 - AGENDA

- 1. Opening
- 2. Appointment of Rapporteur
- 3. Adoption of Agenda
- 4. Review of Status of the WG Recommendations from the February 2014 Meeting
- 5. Development of a framework for the validation of NAFO catch data and generation of catch estimates
- 6. Recommendations to forward to the Fisheries Commission and Scientific Council
- 7. Other matters
- 8. Adoption of the report
- 9. Adjournment

B - FISHERIES COMMISSION AND SCIENTIFIC COUNCIL JOINT WORKING GROUP ON RISK-BASED MANAGEMENT STRATEGIES, 22-24 APRIL 2015 – AGENDA

- 1. Opening
- 2. Appointment of Rapporteur
- 3. Adoption of Agenda
- 4. Review of Status of the WG Recommendations from the February 2014 Meeting
- 5. Discussions on the revision of the NAFO Precautionary Approach Framework
- 6. Discussions on the development of Div. 3NO witch flounder RBMS
- 7. Discussions on the finalization of Div. 3M cod RBMS
- 8. Development of a management strategy for Div. 3LNO Northern shrimp (Pandalus borealis)
- 9. Recommendations to forward to the Fisheries Commission and Scientific Council
- 10. Other matters
- 11. Adoption of the report
- 12. Adjournment

C - SCIENTIFIC COUNCIL MEETING, 29 MAY - 11 JUNE 2015 - AGENDA

- I. Opening (Scientific Council Chair: Don Stansbury)
 - 1. Appointment of Rapporteur
 - 2 Presentation and Report of Proxy Votes
 - 3. Adoption of Agenda
 - 4. Attendance of Observers

- 1. Opening
- 2. Appointment of Rapporteur
- 3. Adoption of Agenda
- 4. Consideration of SC advice from 2015
 - a. Development of work on Significant Adverse Impacts in support of workplan for assessment of bottom fisheries in 2016
 - b. Removal of closed areas from scientific surveys
 - c. Impact of activities other than fishing on fish stocks and biodiversity in the NRA
 - d. Impacts of mid-water trawls on benthic VME indicator species
- 5. Consideration of NCEM Articles 17.1 17.3 (Seamounts)
- 6. Discussion of ongoing matters
 - a. Status of Candidate VME areas 13 and 14 (eastern Flemish Cap)
 - b. Status of Div. 30 Coral Closure
 - c. Significant concentrations of VME indicator species on Tail of the Bank (Div. 3N)
- 7. Implementation of the "Ecosystem Approach"
 - a. Review of the "Roadmap to an Ecosystem Approach"
 - b. Addressing other factors impacting the ecosystem
 - c. Future direction of FC-SC WG-EAFFM
- 8. Other matters
 - a. Coral and Sponge Identification Guide NAFO Area
 - b. Wording of NCEM Article 24
- 9. Recommendations to forward to the Fisheries Commission and Scientific Council
- 10. Adoption of the report
- 11. Adjournment

E - SCIENTIFIC COUNCIL MEETING, 9-16 SEPTEMBER 2015 - AGENDA

- I. Opening (Chair: Don Stansbury)
 - 1. Appointment of Rapporteur
 - 2. Adoption of Agenda
 - 3. Attendance of Observers
 - 4. Plan of Work
- II. Review of Recommendations in 2014
- III. NAFO/ICES Pandalus Assessment Group (Co-chairs Brian Healey and Peter Shelton)
- IV. Formulation of Advice (see Annexes 1–3 of Appendix I)
 - 1. Request from Fisheries Commission (Items 1 of Annex 1)
 - a) Northern shrimp (Div. 3M)
 - b) Northern shrimp (Div. 3LNO)
 - 2. Requests from Coastal States (Items 5 and 6 of Annex 2, Item 2 of Annex 3)
 - a) Northern shrimp (Subareas 0 and 1)
 - b) Northern shrimp (in Denmark Strait and off East Greenland)
- V. Other Matters
 - 1. Scheduling of Future Meetings
 - 2. Topics for Future Special Sessions
 - 3. Other Business
 - a) A tribute to Dave Orr
 - b) Election of chairs
- VI. Adoption of Scientific Council and NIPAG Reports
- VII. Adjournment

F - NAFO/ICES PANDALUS ASSESSMENT GROUP (NIPAG) MEETING, 9-16 SEPTEMBER 2015 - AGENDA

- I. Opening (Co-chairs: Brian Healey and Peter Shelton)
 - 1. Appointment of Rapporteur
 - 2. Adoption of Agenda1
 - 3. Plan of Work
- II. General Review
 - 1. Review of Recommendations in 2014
 - 2. Review of Catches
- III. Stock Assessments
 - Northern shrimp (Division 3M)
 - Northern Shrimp (Divisions 3LNO)
 - Northern shrimp (Subareas 0 and 1)
 - Northern shrimp (in Denmark Strait and off East Greenland)
 - Northern shrimp in Skagerrak and Norwegian Deep (ICES Divisions IIIa and IVa East)
 - Northern Shrimp in Barents Sea and Svalbard area (ICES Sub-areas I & II)
- IV. Other Business
 - FIRMS Classification for NAFO Shrimp Stocks
 - Future Meetings
 - Long-term management strategy for Northern shrimp (Pandalus borealis) in Skagerrak and the Norwegian Deep
 - Chairs of Future Meetings
- V. Adjournment

G - SCIENTIFIC COUNCIL MEETING, 21-25 SEPTEMBER 2015 - AGENDA

364

I. Opening

- 1. Opening
- 2. Appointment of Rapporteur
- 3. Adoption of Agenda
- 4. Plan of Work

a) Joint FC – SC Session

II. Review of Scientific Council Recommendations

III. Research Coordination

- 1. Opening
- 2. Fisheries Statistics
 - a) Progress Reports on Secretariat Activities
 - b) Review of STATLANT21
- 3. Research Activities
 - a) Surveys Planned for 2015 and early 2016
- 4. Other Matters
 - a) Review of SCR and SCS Documents
 - b) Review of Survey SCS Document
 - c) Other Business

IV. Fisheries Science

- 1. Opening
- 2. Nomination of Designated Experts
- 3. Other Matters
 - a) Review of SCR and SCS Documents
 - b) 2016 invited speaker
 - c) Other Business

V. Requests from the Fisheries Commission

- 1. Requests deferred from the June Meeting
 - a) Capelin in Div. 3NO
 - b) Advice on Yellowtail flounder for 2018
- 2. Ad hoc Requests from Current Meeting

VI. Meeting Reports

1. NAFO Joint Fisheries Commission-Scientific Council Working Group on the Ecosystem

Framework for Fisheries Management (WG-EAFFM)

VII. Review of Future Meeting Arrangements

VIII. Future Special Sessions

1. Discussion of proposed topics

IX. Other Matters

1. Report of the NAFO Ad Hoc Working Group on Bycatches, Discards and Selectivity (WG-BDS)

2. Presentation on redfish recruitment

X. Adoption of Reports

1. Committee Reports of STACFIS and STACREC

2. Report of Scientific Council

XI. Adjournment

ANNEX 1. FISHERIES COMMISSION'S REQUEST FOR SCIENTIFIC ADVICE ON MANAGEMENT IN 2015 AND BEYOND OF CERTAIN STOCKS IN SUBAREAS 2, 3 AND 4 AND OTHER MATTERS

1. Fisheries Commission requests that the Scientific Council provide advice for the management of the fish stocks below according to the assessment frequency presented below. The advice should be provided as a range of management options and a risk analysis for each option (rather than a single TAC recommendation).

Yearly basis	<u>Two year basis</u>	<u>Three year basis</u>
Northern shrimp in Div.	American plaice in Div. 3LNO	American plaice in Div. 3M
3LNO	Cod in Div. 3M	Capelin in Div. 3NO
	Redfish in Div. 3LN	Cod in Div. 3NO
	Redfish in Div. 3M	Northern shortfin squid in SA 3+4
	Northern Shrimp in Div. 3M	Redfish in Div. 30
	Thorny skate in Div. 3LNO	Witch flounder in Div. 2J+3KL
	White hake in Div. 3NO	Yellowtail flounder in Div. 3LNO
	Witch flounder in Div. 3NO	

To implement this schedule of assessments, the Scientific Council is requested to conduct the assessment of these stocks as follows:

In 2015, advice should be provided for 2016 for Northern Shrimp in NAFO Div. 3LNO

In 2015, advice should be provided for <u>2016</u> and <u>2017</u> for Cod in Div. 3M and Redfish in Div. 3M, White hake in Div. 3NO.

In 2015, advice should be provided for <u>2016</u>, <u>2017</u> and <u>2018</u> for Cod in Div. 3NO, Yellowtail Flounder in 3LNO and Capelin in Div. 3NO.

Advice should be provided using the guidance provided in **Annexes A or B as appropriate**, or using the predetermined Harvest Control Rules in the cases where they exist.

The Fisheries Commission also requests the Scientific Council to continue to monitor the status of all these stocks annually and, should a significant change be observed in stock status (e.g. from surveys) or in by-catches in other fisheries, provide updated advice as appropriate.

- The Fisheries Commission adopted in 2010 an MSE approach for Greenland halibut stock in Subarea 2 + Division 3KLMNO (FC Document 10/12). This approach considers a survey based harvest control rule (HCR) to set a TAC for this stock on an annual basis. The Fisheries Commission requests the Scientific Council to:
 - a. Monitor and update the survey slope and to compute the TAC according to HCR adopted by the Fisheries Commission according to Annex 1 of FC Document 10/12.
 - b. Advise on whether or not an exceptional circumstance is occurring.
- 3. The Fisheries Commission requests the Scientific Council to analyze and provide advice on management measures that could improve selectivity in the Div. 3M cod and Div. 3M redfish fisheries in the Flemish Cap in order to reduce possible by catches and discards. The objective is to reduce the mixed fisheries between cod and redfish, the by-catch of non-targeted stocks and to analyze if the selectivity pattern could be improved to reduce the catch of undersized fish.
- 4. The Fisheries Commission requests the Scientific Council to continue to develop work on Significant Adverse Impacts in support of the reassessment of NAFO bottom fishing activities required in 2016, specifically an assessment of the risk associated with bottom fishing activities on known and predicted VME species and elements in the NRA.
- 5. Recognizing the work done in NAFO to prevent significant adverse impacts to vulnerable marine ecosystems, and the need for effective stock assessments; Further recognizing that modifications to survey designs occur on regular basis in fisheries surveys in many cases,

FC requests that SC investigate the impacts of removing the closed areas from the survey design for relevant stock surveys.

- 6. For the cod stock in Div. 2J+3KL, the Scientific Council is requested to comment on the trends in biomass and state of the stock in the most recent Science Advisory Report from the Canadian Science Advisory Secretariat.
- 7. The Fisheries Commission requests the Scientific Council to conduct a full assessment of witch flounder in Div. 3NO.
- 8. Please provide a stock assessment for Alfonsino, and recommendation.
- 9. Could the SC liaise with the national institutes of the different CPs to see if as recommended by STACFIS acoustic surveys for capelin can be carried out?
- 10. There are some spatial and depth coverage deficiencies in the Greenland Halibut survey. It is suspected that there is a component of the Greenland Halibut stock of age-class 14+ that lives in depths under 1 500 meters and is therefore inaccessible to scientific trawling. Please:
 - a. comment on this hypothesis;
 - b. indicate if information on this part of the stock would be useful for the stock assessment and the understanding of the stock dynamics;
 - c. indicate if there are techniques available to assess the biomass below 1 500 meters, and;
 - d. if useful and possible, implement such techniques in view of the next stock assessment.
- 11. The NAFO 2011 Performance Review Panel encouraged NAFO to consider whether activities other than fishing in the NAFO Convention Area may impact the stocks and fisheries for which NAFO is responsible as well as biodiversity in the NAFO Regulatory Area. Such activities might include oil exploration, shipping and recreational activities. Some work has been carried out as part of the ecosystem approach.

As the first step in the assessment of such impacts and for the implementation of the priorities of the Ecosystem Roadmap, could the Scientific Council provide a literature survey that would indicate what the risks are to the fish stocks and ecosystems in the NAFO Regulatory Area by looking at comparable situations.

12. The Fisheries Commission requests the Scientific Council to evaluate the impact of mid-water trawls on VME indicator species in those instances when the gear makes contact with or is lost on the bottom.

ANNEX A: GUIDANCE FOR PROVIDING ADVICE ON STOCKS ASSESSED WITH AN ANALYTICAL MODEL

The Fisheries Commission request the Scientific Council to consider the following in assessing and projecting future stock levels for those stocks listed above. These evaluations should provide the information necessary for the Fisheries Commission to consider the balance between risks and yield levels, in determining its management of these stocks:

- 1. For stocks assessed with a production model, the advice should include updated time series of:
 - Catch and TAC of recent years
 - Catch to relative biomass
 - Relative Biomass
 - Relative Fishing mortality
 - Stock trajectory against reference points
 - And any information the Scientific Council deems appropriate. Stochastic short-term projections (3 years) should be performed with the following constant fishing mortality levels as appropriate:
 - For stocks opened to direct fishing: 2/3 F_{msy}, 3/4 F_{msy}, 85% F_{msy}, 75% F₂₀₁₄, F₂₀₁₄, 125% F₂₀₁₄,
 - For stocks under a moratorium to direct fishing: F₂₀₁₄, F = 0. The first year of the projection should assume a catch equal to the agreed TAC for that year.

Results from stochastic short term projection should include risks of stock population parameters increasing above or falling below available biomass and fishing mortality reference points. The table indicated below should guide the Scientific Council in presenting the short term projections.

				$P(F > F_h)$	im)		P(<i>B<b< i="">)</b<></i>	im)		P(<i>F</i> > <i>F</i> _m	sy)		P(<i>B</i> < <i>B</i> ,	_{nsy} P		P(B ₂₀₁₇ > B ₂₀₁₄)

F=0	t	t	t	%	%	%	%	%	%	%	%	%	%	%	%	%

Limit reference points

- 2. For stock assessed with an age-structured model, information should be provided on stock size, spawning stock sizes, recruitment prospects, historical fishing mortality. Graphs and/or tables should be provided for all of the following for the longest time-period possible:
 - historical yield and fishing mortality;
 - spawning stock biomass and recruitment levels;
 - Stock trajectory against reference points

And any information the Scientific Council deems appropriate

Stochastic short-term projections (3 years) should be performed with the following constant fishing mortality levels as appropriate:

- For stocks opened to direct fishing: F_{0.1}, F_{max}, 2/3 F_{max}, 3/4 F_{max}, 85% F_{max}, 75% F₂₀₁₄, F₂₀₁₄, 125% F₂₀₁₄,
 For stocks under a moratorium to direct fishing: F₂₀₁₄, F = 0.
- The first year of the projection should assume a catch equal to the agreed TAC for that year.

Results from stochastic short term projection should include:

- The 10%, 50% and 90% percentiles of the yield, total biomass, spawning stock biomass and exploitable biomass for each year of the projections
- The risks of stock population parameters increasing above or falling below available biomass and fishing mortality reference points. The table indicated below should guide the Scientific Council in presenting the short term projections.

Limit reference points

ANNEX B. GUIDANCE FOR PROVIDING ADVICE ON STOCKS ASSESSED WITHOUT A POPULATION MODEL

For those resources for which only general biological and/or catch data are available, few standard criteria exist on which to base advice. The stock status should be evaluated in the context of management requirements for long-term sustainability and the advice provided should be consistent with the precautionary approach.

The following graphs should be presented, for one or several surveys, for the longest time-period possible:

- a) time trends of survey abundance estimates
- b) an age or size range chosen to represent the spawning population
- c) an age or size-range chosen to represent the exploited population
- d) recruitment proxy or index for an age or size-range chosen to represent the recruiting population.
- e) fishing mortality proxy, such as the ratio of reported commercial catches to a measure of the exploited population.
- f) Stock trajectory against reference points

And any information the Scientific Council deems appropriate.

ANNEX 2. DENMARK (ON BEHALF OF GREENLAND) REQUEST FOR SCIENTIFIC ADVICE ON MANAGEMENT IN 2015 OF CERTAIN STOCKS IN SUBAREAS 0 AND 1

- 1. For Roundnose grenadier in Subarea 0 + 1 advice was in 2014 given for 2015-2017. Denmark (on behalf of Greenland) requests the Scientific Council to continue to monitor the status of Roundnose grenadier in Subareas 0 and 1 annually, and should significant changes in the stock status be observed (e.g. from surveys) the Scientific Council is requested to provide updated advice as appropriate.
- 2. Advice for golden redfish *(Sebastes marinus)*, demersal deep-sea redfish *(Sebastes mentella)* American plaice *(Hippoglossoides platessoides)*, Atlantic wolffish *(Anarhichas lupus)* and spotted wolffish *(A. minor)* in Subarea 1 was in 2014 given for 2015-2017. Denmark (on behalf of Greenland) requests the Scientific Council to continue to monitor the status of these species annually, and should significant changes in stock status be observed the Scientific Council is requested to provide updated advice as appropriate.
- 3. Subject to the concurrence of Canada as regards Subareas 0 and 1, the Scientific Council is requested to provide advice on appropriate TAC levels for 2016 separately for Greenland halibut in 1) the offshore areas of NAFO Division 0A and Division 1A plus Division 1B and 2) NAFO Division 0B plus Divisions 1C-1F. The Scientific Council is also asked to advice on any other management measures it deems appropriate to ensure the sustainability of these resources.
- 4. Advice for Greenland halibut in Division 1A (inshore) was in 2014 given for 2015-2016. Denmark (on behalf of Greenland) requests the Scientific Council to continue to monitor the status of Greenland halibut in Division 1A (inshore) annually, and should significant changes in stock status be observed, the Scientific Council is requested to provide updated advice as appropriate.
- 5. Subject to the concurrence of Canada as regards Subarea 0 and 1, Denmark (on behalf of Greenland) further requests the Scientific Council before December 2015 to provide advice on the scientific basis for management of Northern shrimp *(Pandalus borealis)* in Subarea 0 and 1 in 2015 and for as many years ahead as data allows for.
- 6. Furthermore, the Scientific Council is in cooperation with ICES requested to provide advice on the scientific basis for management of Northern shrimp *(Pandalus borealis)* in Denmark Strait and adjacent waters east of southern Greenland in 2016 and for as many years ahead as data allows for.

ANNEX 3. REQUESTS FOR ADVICE FROM CANADA

- 1) The Scientific Council is requested, subject to the concurrence of Denmark (on behalf of Greenland) as regards Subarea 1, to provide an overall assessment of status and trends in the total stock area throughout its range and to specifically advise on TAC levels for 2016, separately, for Greenland halibut in Divisions 0A+1A (offshore) and 1B, and Divisions 0B+1C-F.⁷ The Scientific Council is also asked to provide advice on any other management measures it deems appropriate to ensure the sustainability of these resources.
 - a. It is noted that at this time only general biological advice and/or catch data are available, few standard criteria exist on which to base advice. The stock status should be evaluated in the context of management requirements for long-term sustainability and the advice provided should be consistent with the precautionary approach and include likely risk considerations and implications as much as possible, including risks of maintaining current TAC levels and any risks and available details of observations that would support an increase or decrease in the TACs.
 - b. Recognizing that this is a data poor fishery, and that no model exists at this time to provide riskbased advice to inform management options, the Scientific Council is also asked to identify what would be required in order to provide risk based advice in the future.

The following graphs should be presented, for one or several surveys, for the longest time-period possible:

- historical catches;
- abundance and biomass indices;
- an age or size range chosen to represent the spawning population;
- an age or size range chosen to represent the exploited population;
- recruitment proxy or index for an age or size-range chosen to represent the recruiting population;
- fishing mortality proxy, such as the ratio of reported commercial catches to a measure of the exploited population;
- stock trajectory against reference points
- Any other information the Scientific Council feels is relevant should also be provided.
- 2) Canada requests the Scientific Council to consider the following options in assessing and projecting future stock levels for Shrimp in Subareas 0 and 1:
 - a) The status of the stock should be reviewed and management options evaluated in terms of their implications for fishable stock size, spawning stock size, recruitment prospect, catch rate and catch over the next 5 years. The implications of catch options ranging from 30,000t to the catch corresponding to Z MSY, in 5,000 t increments, should be forecast for 2016 through 2020 if possible, and evaluated in relation to precautionary reference points of both mortality and fishable stock biomass. Results should include a partitioning of the future estimable removals between catches and estimable predation for the various catch options requested. The present stock size and fishable stock size should be described in relation to those observed historically and those to be expected in the next 5 years under the various catch options requested, and any other options Scientific Council feels worthy of consideration.
 - b) Management options should be provided within the Northwest Atlantic Fisheries Organization Precautionary Approach Framework. Uncertainties in the assessment should be evaluated and presented in the form of risk analyses related to the limit reference points of B_{lim} and Z_{MSY} .

⁷ The Scientific Council has noted previously that there is no biological basis for conducting separate assessments for Greenland halibut throughout Subareas 0-3, but has advised that separate TACs be maintained for different areas of the distribution of Greenland halibut.

- c. Presentation of the results should include the following:
 - a graph and table of historical yield and fishing mortality for the longest time period possible;
 - a graph of biomass relative to B_{MSY}, and recruitment levels for the longest time period possible.
 - a graph of the stock trajectory compared to B_{lim} and/or B_{MSY} and $Z_{MSY}.;$
 - graphs and tables of total mortality (Z) and fishable biomass for a range of projected catch options (as noted in 2 a) for the years 2016 to 2020 if possible. Projections should include both catch options and a range of cod biomass levels considered appropriate by SC. Results should include risk analyses of falling below B_{MSY} and B_{lim}, and of exceeding Z_{MSY}.;
 - a graph of the total area fished for the longest time period possible; and
 - any other graph or table the Scientific Council feels is relevant.
- 3) Canada requests the Scientific Council to explore the impact of proposed harvest strategies that would maintain the North Atlantic harp seal population at a precautionary level of a PA framework, using the Canadian levels as a case study, and that would have a low risk of decreasing below the critical level. (Received 7 July 2014)

MERIT AWARDS

Year	Recipient	Institute
2009	Ralph Mayo	NMFS Woods Hole, MA, USA
2010	Dr. Manfred Stein	Institut fur Seefischerei, Hamburg, Germany
2011	Dr. Vladimir Rikhter	AtlantNIRO, Kaliningrad
2013	Bill Brodie	DFO, St. John's, NL, Canada
2013	Jean-Claude Mahé	IFREMER Lorient, France
2013	Antonio Vázquez	Spain, European Union
2014	Fred Serchuk	Northeast Fisheries Science Center (NEFSC), USA

LIST OF RECOMMENDATIONS IN 2015

From the Joint FC-SC Ad hoc Working Group on Catch Reporting(WG-CR) – 20 -21 April 2015

Recommendations to forward to the Fisheries Commission and Scientific Council

It is **recommended**:

- 2. that SC and FC give consideration to the establishment of the Catch Data Advisory Group and adopt its Terms of Reference (Annex 3); and
- 3. that SC and FC or an appropriate subsidiary body review the utility of data collection more generally, noting that some newer data sets provide more reliable and/ or timely information, making others redundant.

From the Joint FC-SC Working Group on Risk-Based Management Strategies (WG-RBMS) - 22-24 April, 2015

9. Recommendations to forward to the Fisheries Commission and Scientific Council

The Working Group **recommends that**:

- 1. Scientific Council convenes a technical working group which could explore the revision of the precautionary approach.
- 3. Scientific Council gives a high priority to development of reference points for all stocks which lack them.
- 4. Scientific Council performs a review of the Div. 3M cod MSE.
- 5. Scientific Council discusses the following HCR options for Div. 3M cod:
 - a. Starting points
 - i. F_{status quo}
 - ii. 40% reduction
 - b. An HCR which meets management objectives 1 (very low risk of breaching B_{lim}) and 2 (low risk of overfishing) within five years, and within ten years, with:
 - i. risk calculated for each year in the time series
 - ii. risk calculated for the end of the periods (final year)
 - iii. risk averaged over the periods

390

The recommendations made by STACFEN for the work of the Scientific Council as **endorsed** by the Council, are as follows:

- STACFEN **recommends** consideration of support for one invited speaker to address emerging issues and concerns for the NAFO Convention Area during the 2016 STACFEN Meeting.
- STACFEN **recommends** that a sub-committee of STACFEN members be formed to discuss and draft a plan towards the reconfiguration and/or amalgamation of STACFEN and WGESA to be presented at the 2015 STACFEN Meeting.
- STACFEN **recommends** that a sub-committee of STACFEN members be formed to discuss the current state of Fisheries and Oceans Canada (DFO) Oceanographic Services (formerly ISDM and MEDS) data management responsibilities to NAFO and related mechanisms for the reporting of oceanographic data by member states and the subsequent means of accessing these data.

The recommendations made by STACPUB for the work of the Scientific Council as **endorsed** by the Council, are as follows:

- STACPUB **recommends** that the Secretariat contact WGESA for further instruction on the VME Guides in order to publish it for September 2015.
- STACPUB **recommends** that Scientific Council consider holding another symposium and that a list of potential topics and themes be put forward.
- STACPUB **recommends** that the NAFO Secretariat look into this matter, update their current list of SC members and create a forum for the electronic exchange of ideas that is accessible to SC members

The recommendations made by STACREC for the work of the Scientific Council as **endorsed** by the Council, are as follows:

- STACREC **recommends** that the NAFO Secretariat develop a framework for communicating tagging study information to vessels from Contracting Parties and Coastal States fishing in the Convention Area (e.g., via a link to this information on the NAFO website homepage).
- STACREC **recommends** that the Scientific Council support the EU H2020-BG02-2015 proposal "Predicting consequences of climate change on Aquatic FOOD production (AFOOD)" and agrees to serve on the external advisory board.

The recommendations made by STACFIS for the work of the Scientific Council as **endorsed** by the Council, are as follows:

There were no general recommendations arising from STACFIS

From STACFIS

4. Redfish in SA1

STACFIS reiterated the **recommendation** that *the species composition and quantity of redfish discarded in the shrimp fishery in SA 1 be further investigated.*

05b. American plaice in Subarea 1

STACFIS reiterated the **recommendation** that the species composition and quantity of American plaice discarded in the shrimp fishery in SA1 be further investigated.

STACFIS reiterated the **recommendation** that the distribution of these species in relation to the main shrimpfishing grounds in SA1 be investigated, in order to further discover means of reducing the amount of discarded American plaice in the by-catch.

6. Cod in Div. 3M

STACFIS **recommended** that an age reader comparison exercise be conducted.

STACFIS **recommended** that the most recent catch at age figures will revised.

7. Redfish in Div. 3M

STACFIS **recommended** that, in order to quantify the most likely redfish depletion by cod on Flemish Cap, and be able to have an assessment independent approach to the magnitude of such impact by species and to the size structure of the redfish most affected by cod predation, the existing feeding data from the past EU surveys be analyzed on a refined scale.

STACFIS also **recommends** that this important line of ecosystem research based on the feeding sampling routine of the EU survey catch be done on an annual basis.

8. American plaice in Div. 3M

STACFIS **recommends** that several input frameworks be explored in both models (such as: q's; M (e.g. in relation to $F_{0,1}$); ages dependent of the stock size; the proxies and its distribution in the VPA-type Bayesian model).

Due to the recent improved recruitment at low SSB, STACFIS **recommends** *to explore the Stock/Recruitment relationship and Blim*.

9. Cod (Gadus morhua) in Divs. 3NO

STACFIS **recommended** continuing to monitor the consistency in trends between the Canadian and EU-Spain surveys.

STACFIS **recommends** *investigating the potential use of a plus group in the assessment model.*

11. American plaice in Div. 3LNO

STACFIS **recommended** that *investigations* be undertaken to compare ages obtained by current and former Canadian age readers.

STACFIS **recommends** that *investigations* be undertaken to examine the retrospective pattern and take steps to improve the model.

12. Yellowtail flounder (Limanda ferruginea) in Divs. 3LNO

STACFIS **recommends** that further work be undertaken to better understand the uncertainties estimated in the ASPIC model.

14. Capelin in Div. 3NO

STACFIS reiterates its **recommendation** that initial investigations to evaluate the status of capelin in Div. 3NO should utilize trawl acoustic surveys to allow comparison with the historical time series.

15. Redfish in Div. 30

STACFIS **recommended** that for Redfish in Div. 30, a recruitment index be developed for this stock.

17. White hake in Div. 3NO

STACFIS **recommended** that age determination should be conducted on otolith samples collected during annual Canadian surveys (1972-2014+); thereby allowing age-based analyses of this population.

STACFIS **recommended** that the collection of information on commercial catches of white hake be continued and now include sampling for age, sex and maturity to determine if this is a recruitment fishery.

STACFIS **recommended** that survey conversion factors between the Engel and Campelen gear be investigated for this stock.

STACFIS **recommends** that work continue on the development of population models and reference point proxies.

20. Greenland Halibut (Reinhardtius hippoglossoides) in SA 2 + Divs. 3KLMNO

STACFIS **recommended** that methods for estimating catch for 2011-2014 be explored for Greenland Halibut in SA 2 + Divs. 3KLMNO, including where ever possible the utility of using effort in conjunction with estimates of catch per unit effort.

21. Northern shortfin squid in SA 3+4

STACFIS **recommended** that gear/vessel conversion factors be computed to standardize the 1970-2003 relative abundance and biomass indices from the July Div. 4VWX surveys.

From the FC-SC WGEAFFM, 15-17 July 2015

9. Recommendations to forward to the Fisheries Commission and Scientific Council

The Working Group **recommends**:

In relation to Progress of the Workplan on SAI in support of reassessment of bottom fisheries in 2016:

- that Scientific Council should take into account the protection afforded to VME areas outside the NAFO fisheries footprint in the calculation of the VME area and biomass at risk of bottom fishing impact;
- 2. that Scientific Council refine VME kernel density analysis polygon boundaries, taking into account current understanding of distribution patterns in relation to environmental variables.

In relation to removal of closed areas from scientific surveys:

3. that Scientific Council considers options to expedite a risk assessment of trawl surveys impact on VME in closed areas, and the effect of excluding surveys from these areas on stock assessments.

In relation to Other matters:

8. that Scientific Council consider widening the scope of the NAFO coral and sponge identification guides to include other relevant species on seamounts.

From the NIPAG Meeting, 9-16 September 2015

1. Northern Shrimp in Div. 3M

For Northern Shrimp in Div. 3M NIPAG **recommends** that further exploration of the relationship between shrimp, cod and the environment be continued in WGESA and NIPAG encourages the shrimp experts to be involved in this work.

2. Northern Shrimp (Pandalus borealis) in Div. 3LNO

NIPAG **recommended** that ecosystem information related to the role of shrimp as prey in the Grand Bank (i.e. 3LNO) Ecosystem be presented to the 2016 NIPAG meeting.

3. Northern Shrimp in SA 0+1

NIPAG recommended that:

- given that the CPUE series for the Greenland sea-going and coastal fleets continue to agree while neither agrees with changes in the survey estimates of biomass since 2002, possible causes for change in the relationship between fishing efficiency and biomass should be investigated;
- the relationship between estimated numbers of small shrimps and later estimates of fishable biomass should be investigated anew.

Survey trends inshore and offshore are divergent and NIPAG **recommends** *exploration of the nature and implications of this divergence.*
