SCIENTIFIC COUNCIL MEETING - JUNE 1982

Assessment Update for the Yellowtail Stocks in Divisions 3LNO

by

W. B. Brodie and T. K. Pitt
Research and Resource Services
Department of Fisheries and Oceans
P. O. Box 5667
St. John's, Newfoundland A1C 5X1

INTRODUCTION

This stock has been under quota regulation since 1973. Nominal catches by country for the period 1966-81 and TAC's for 1973-82 appear in Table 1. Tables 2 and 3 give the nominal catches by division and catch-effort data respectively for the years 1966-81. Approximately two-thirds of the TAC was taken in both 1980 and 1981, owing to a significant reduction in directed effort for yellowtail in both years.

Stock Assessment

Sampling: The length measurements and otolith samples listed in Table 4 were provided by the Canadian Commercial Groundfish Sampling Section in St. John's.

Numbers at age: These were calculated in the usual manner by applying quarterly age-length keys (sexes separate) to monthly frequencies for each NAFO Division. Total numbers caught at age were obtained by combining male and female numbers from all Divisions. Numbers at age for 1968-81 are in Table 5.

Weight at age: Average weights at age for 1981 were obtained by applying a length-weight equation to monthly average lengths (weighted by the number caught at age). Weights at age for 1968-81 are in Table 6.

Partial recruitment: Three versions of partial recruitment were used in this assessment (Table 7):

PR Ave - Derived from average F's from cohort (1968-76) and, when used in yield per recruit calculations with average weights (1968-74) produces a value of 0.52 for $F_{0.1}$ (Brodie and Pitt, 1981).

PR1 - Same as PR ave for ages 5-10. PR at age 4 was adjusted to give a population at age 4 in the VPA approximately equal to the geometric mean of age 4 population, 1968-81.

PR2 - Derived from a cohort run using catch-at-age for 1978-81. The values represent the average of the fishing mortality in 1979 and 1980, standardized at age 9. The value for age 4 was adjusted by the ratio of the catch at age 4 in 1980 to 1981.

Virtual Population Analysis: Two separate analyses were carried out - one using PR1 and a range of terminal F's from 0.4 to 0.5 and one using PR2 and F_t's between 0.6 and 1.0. Results were as follows:

Option 1 (PR1 used): Terminal F was determined by regressions of 4+ Biomass on CPUE (Table 8) and F(ages 4-10) on effort (Table 9). The correlation coefficient r decreased slightly as F_t increased from .4 to .5. The best predicted value for 1981 biomass came from a VPA run with F_t between .45 and .5 (Fig. 2). In the regression of F on effort, r once again decreased marginally as F_t increased with the best predicted value for weighted F in 1981 coming from the VPA run initiated by F_t = .5 (Fig. 3).

Option 2 (PR2 used): This analysis was calibrated using the same criteria used above. Regression of 4+ biomass on CPUE (Table 10) showed that r was highest for the values at $F_t = .7$ but that the predicted value for 1981 was closest for the run at $F_t = .9$. F on effort (Table 11) revealed that r decreased as F_t increased and that the best predicted value for 1981 came from the regression using VPA values from the run at $F_t = 1.0$. The fact that the 1968-80 regression line passes through the origin at some value of terminal F between 0.8 and 0.9 also may be of some value here.

The option 1 VPA at $F_t = .45$ is presented in Tables 12a-c and the Option 2 VPA at $F_t = .9$ is shown in Tables 13a-c.

Research Vessel Surveys: Results of research vessel surveys in Divisions 3L and 3N are presented in Tables 14 and 15. The omission of a key stratum, 361, (Fig. 1) in 1981 precluded the use of the survey data in tuning the virtual population analysis.

Recruitment: The 1968-77 geometric mean of age 4 numbers from the option 2 VPA at $F_T = 0.90$ was used to estimate recruitment for projections to 1983. This value was 100×10^6 fish.

DISCUSSION

Abundance indices: Catch per unit effort from Canada (N) otter trawlers, tonnage class 5 showed a steady increase between 1976 and 1980, with a slight drop in 1981 to a level of 0.614 t/hr (Table 3). Research vessel surveys indicate a fairly stable population size since 1978, with the numbers for 1981 being biased downward by the omission of a key stratum from the 1981 survey. Estimation of year class strength from the research vessel survey data is practically impossible since yellowtail of age 4 and less are not fully recruited to the research gear.

Virtual Population Analysis: A comparison of the population numbers in 1981 from both VPA runs (Tables 12a and 13a) showed little difference, as would be expected.

Catch Projections: Tables 16a-16e show the results of a projection to 1983, using the 1981 population from the VPA run at $F_t = .90$. Long-term (1968-74) average weights (Table 6) were found to be close to current average weights and were therefore used in projecting. PR Ave (Table 7) was also used. Assuming that 23,000 t will be removed in 1982, the projected catch in 1983 at $F_{0.1} = .518$ would be approximately 19,000 t.
