St. John's, Newfoundland A1C 5X1

INTRODUCTION

Analytical assessment techniques have not been used in recent years due to the lack of catch at age data. Up until 1979 the general production model was commonly used for the 2+3 stock but since then the regressions of catch rate on effort have not been significant. Much discussion has been centred around the catch rate series which has shown a fairly steady decline since about 1975. USSR scientists have indicated that the declining catches and catch rates are not indicative of stock status but are more reflective of the by-catch restrictions coupled with an increase in the turbot population. In 1982, while acknowledging the comments of the USSR scientists, STACFIS concluded that the continuing downward trend in catch rates could not be ignored. As a result, the TAC was lowered from the 1982 level of 27,000t to 11,000t in 1983.

In recent years the grenadier fishery in Subareas 0+1 has been a by-catch fishery and no updated assessments have been carried out.

METHODS AND RESULTS

Nominal catches for the two stocks are shown in Table 1 and are illustrated in Fig. 1 for the 2+3 stock. In Subareas 0+1 catches peaked at about 12,000t in 1974 but have declined since then to a low of 18t in 1982. Since their imposition in 1975, the TAC's have never been achieved. The fact that there has been little to no directed fishery for grenadier in this area since 1979 precludes any assessment.

Grenadier catches in Subareas 2+3 show a marked drop from 1979 onwards when compared with those of earlier years. This decline is partly related to a decline in the standardized effort as seen in Fig. 2.

The multiplicative model (Gavaris 1980) was again used to standardize the catch rate. The Foreign Observer Program (F.O.P.) data were available for 1982 although they accounted for only 9% of the total reported catch. The results of the regressions (Table 2) indicate that they are significant. The standardized (to 1967) catch rates and effort are shown in Table 3 and Fig 2 and 3. It can be seen that catch rates continued to drop in 1982.

Regressions of CPUE on effort with and without the 1971 point (Table 4a and b respectively) show no correlation and thus once again the general production model cannot be used.

The above data do not provide any new insights into the status of roundnose grenadier in Subareas 2+3 and based upon these no change can be suggested for the 1984 TAC from that of 1983.
