Stomach contents of the Atlantic wolffish, *Anarhichas lupus*,
from the Northwest Atlantic

by

10

Abstract

11 Stomach contents of Atlantic wolffish (*Anarhichas lupus*), collected in the
12 Northwest Atlantic from West Greenland to the Scotian Shelf, were examined by
13 volume and by occurrence. Invertebrates made up 85% of the food and fish 15%.
14 The most important invertebrates in order were: molluscs, especially whelks
15 and Iceland scallops; echinoderms, particularly brittle stars and sea urchins;
16 and crustacea, mainly crabs. Redfish formed the predominant fish food.
17 Molluscs increased and echinoderms usually decreased in importance from the
18 smaller to the larger wolffish.

19

Introduction

1

2 The food of *Anarhichas lupus* was studied for the Labrador-Newfoundland
3 region by Albikovskaya (1983), and off Iceland by Pálsson (1983). Notes on
4 the food of this species were recorded by Verrill (1871), Smith (1889, 1890,
5 1891, 1892), Scott (1902, 1903), Gill (1911), Bigelow and Schroeder (1953),
6 Barsukov (1959), Jónsson (1982), and others.

7

Materials and Methods

8

9 Stomach contents of 103 Atlantic wolffish were examined in the field for
10 volumes of various food items. Classification was limited in detail to species
11 or groups readily identified in the field without further detailed
12 investigation. Volumetric measurements of the different food items in the
13 stomachs were made by displacement of water in a graduated cylinder. An
14 additional 44 stomachs containing food were examined qualitatively. The
15 numbers of Atlantic wolffish stomachs containing food, by length range from

16 various NAFO divisions, are listed on Table 1, and the localities from which
17 Atlantic wolffish were sampled in wolffish studies generally are shown in
18 Templeman (MS 1984). The wolffish were measured as greatest total length with
19 the mouth closed.

20 Results

21
22 Of the 103 Atlantic wolffish stomachs examined for food volume, in this
23 paper, 31% contained food (Table 2). It was apparent that bottom invertebrates
24 formed the main food with whelks 22%, Iceland scallops 12%, crabs 12%, hermit
1 crabs 11% and brittle stars 16%. Invertebrates made up 85% of the food.
2 Redfish with 12% was the main item of the 15% fish food.

3 In qualitative examination of 76 stomachs containing food (Table 3),
4 invertebrates were again predominant with whelks in 46%, scallops in 12%, sea
5 urchins in 30%, hermit crabs in 20%, other crabs in 13% and brittle stars in
6 20% of the stomachs. Redfish were present in 9% of the stomachs.

7 Sea urchins and whelk shells in the stomachs were often crushed and some
8 whelks were recorded without their shells. Molluscs, especially whelks and
9 Iceland scallops, increased and echinoderms usually decreased in importance
10 from the smaller to the larger fish. Fish were more plentiful as food in the
11 larger than in the smaller length ranges.

12 Discussion

13
14 The stomach contents of the Atlantic wolffish from the various authors
15 previously quoted, and especially from Pálsson (1983), Albikovskaya (1983)
16 and Jónsson (1982) consisted mainly of benthic invertebrates with only a
17 small amount of fish. The benthic invertebrate food consisted chiefly of
18 echinoderms, especially ophiuroids, molluscs, especially gastropods, and
19 crustacea, mainly crabs and hermit crabs. The predominance of these varieties
20 of food and of their species depended on their abundance in the locality where
21 the wolffish lived.

22 The results presented in this paper were generally similar to those of
23 previous studies, but with molluscs, especially gastropods, predominant
24 followed by echinodermata, especially ophiuroids and sea urchins, and
25 crustacea, mainly crabs and hermit crabs.
