SCIENTIFIC COUNCIL MEETING - JUNE 1984

Redfish in NAFO Divisions 3LN

by

D. B. Atkinson

Fisheries Research Branch, Department of Fisheries and Oceans
P. O. Box 5667, St. John's, Newfoundland A1C 5X1

INTRODUCTION

The data available for this stock are very limited. The present TAC is 25,000 t and the long-term average catch is about 22,000 t. In recent years, the general production model has not been used since regressions of CPUE on effort are not significant without the anomalous 1968 and 1974 points. Catch curves based on a Canadian research survey to the area in 1979 suggested fishing at an F of about 0.12.

METHODS AND RESULTS

From the mid-1970's on, Canada has taken the majority of the landings in Div. 3L (Table 1a) while the USSR has predominated in the fishery in Div. 3N (Table 1b). The fishery is prosecuted throughout the year (Tables 2a, 2b) in both Divisions. A summary of historical catches (Table 3) indicates that in most years the greatest proportion of redfish is taken in Div. 3N. The catches for the stock area are summarized in Fig. 1.

The multiplicative model (Gavaris 1980) was used to standardize the catch rate series to 1959. Categories of vessel class-country-gear, month, and Divisions were used in an unweighted regression. The results (Table 4) indicate significance and the resultant standardized CPUE and effort are shown in Table 5 and Fig. 2 and 3. Effort has remained fairly constant since the mid-1970's but the catch rate approximately doubled between 1979 and 1980 but has remained reasonably stable since. Except for this increase between 1979 and 1980, and the anomalously low 1968 and 1974 points, the catch rates have remained quite stable throughout the history of this fishery. Regressions of CPUE on effort with and without the 1968 and 1974 points (Tables 6a and b) indicate that the past problems with correlation still exist and the general production model is still not feasible.

The commercial frequencies available from the 1983 fishery (Fig. 4-8) are reflective of the fact that the majority of the Canadian fishery is conducted in 3L. These all indicate fish of 25-35 cm predominating in the catches from Div. 3L. The smaller fish recorded by the USSR (Fig. 7) were also present in their Div. 3N sample suggesting that fishing was taking place in the vicinity of the 3L-3N boundary.

There are no new research data available for this stock.

DISCUSSION

The overall lack of data precludes any indepth analysis of this stock. Except for the sudden jump in catch rates between 1979 and 1980, the catch rates have shown remarkable stability over the history of this fishery. Whether the sudden increase in 1980 to a higher, possibly stable level is due to an increase in stock biomass or some other reason is unknown at present but sudden increases of this magnitude in redfish biomass are not to be expected. There is nothing in the limited data to suggest pessimism concerning this stock. The data do not suggest a change in the 1985 TAC from the present level of 25,000 t.
