Minimum Estimates of Abundance of Arctic cod (Boreogadus saida) in
NAFO Divisions 2J, 3K, and 3L from Research Vessel Surveys

by

W. H. Lear and J. W. Baird
Fisheries Research Branch, Department of Fisheries and Oceans
P. O. Box 5667, St. John's, Newfoundland A1C 5X1

INTRODUCTION

Arctic cod (Boreogadus saida) occur in the Newfoundland-Labrador area and are distributed along the Labrador coast, off the east coast of Newfoundland and on the northern part of the Grand Bank (Lear 1979). Up to the present there has been no attempt made to estimate their abundance, based on research vessel surveys for groundfish. Miller (1979) reported an acoustic estimate of about 90,000 t of young-of-the-year arctic cod from a sampled area of 32,591 square kilometers in NAFO Div. 2J and 3K during October 1978.

The aim of this paper is to present the biomass estimates of arctic cod as determined from otter trawls fished on the bottom using a random-stratified design currently used for groundfish. These estimates represent bare minima and may be only indices of abundance of the larger arctic cod, which occur near the bottom, in view of the pelagic nature of arctic cod distribution and their vertical distribution in the water column (Lear 1979; Bain and Sekerak 1978).

RESULTS AND DISCUSSION

Research vessel surveys of random-stratified design were conducted by the GADUS ATLANTICA in NAFO Div. 2J during autumn 1977-84 and in Div. 3K during autumn 1978-84 (Table 1). Spring surveys were conducted by the A.T. CAMERON in NAFO Div. 3L during 1971-82. Summer-autumn surveys were conducted by the A.T. CAMERON during 1971, 1981 and 1982 and by the WILFRED TEMPLEMAN during 1983 and 1984.

The estimates of abundance (numbers) during 1977 to 1984 in NAFO Div. 2J varied from 6.6 million in 1978 to 75.4 million in 1979 (Table 2). The strata where arctic cod occurred in significant abundance each year were mainly in the 101-200 m and 201-300 m depth zones, namely 201, 202, 205, 206, 207, 209, and 234 which are the areas within the influence of the cold Labrador current on the central and inside part of Hamilton Bank, coastal zone of Labrador and in Hawke Channel (Fig. 1). Estimates of biomass (t) show a similar pattern (Table 3). Generally, the estimated trawlable biomass of arctic cod in Div. 2J varies from about 200 to 1000 t based on the autumn groundfish surveys. The confidence limits around the abundance and biomass estimates were large in most years.

The estimates of abundance (Table 4) and biomass (Table 5) for NAFO Div. 3K, based on autumn surveys, displayed considerable annual fluctuations. The estimates of numbers, although subject to wide confidence limits, varied during 1978 to 1984 from less than one million to about 26 million individuals while the biomass estimates ranged from 18 to 974 t. The strata of highest abundance during most years were 620, 621, 628, and 629 which is mainly the coastal shelf off northern Newfoundland and the inside slopes of Funk Island Bank (Fig. 2). Stratum, 619 which was surveyed for the first time in 1984, also had a good index of abundance of arctic cod.

Estimates of abundance (Table 6) and of biomass (Table 7) from spring surveys during 1971-82 in NAFO Div. 3L were lower than those in 2J and 3K although there was an estimate of 19 million individuals during 1974. In other years the numbers varied from 0 to 7 million but were generally less than one million. The estimates of biomass varied from 0 to 197 t. The largest catches of arctic cod during the spring cruises occurred in strata 341, 344, 347, 348, and 349 which are on the northwestern Grand Bank, Avalon Channel, and the shoreward, cooler areas of the Grand Bank (Fig. 3).

Abundance (Table 8) and biomass (Table 9) estimates of arctic cod in NAFO Div. 3L during summer-autumn surveys during 1971, 1981-84 varied from 295,000 to 4.5 million fish and from 13 to 197 t although the confidence limits were large. The greater estimates during 1981-84 over those of 1971 are a reflection of greater coverage during recent years.

The overall biomass estimates for Div. 2J were generally higher than those of 3K but there was no parallel between the catches in the same year. For 1979, 1980, 1981, 1983, and 1984 these were in reverse order (Fig. 4). Generally, however, the abundance estimates during autumn in 3L although lower, followed the same trend, as those of 3K during 1981-84.
