SCIENTIFIC COUNCIL MEETING - SEPTEMBER 1986

An Assessment Update of the Cod Stock in NAFO Divisions 3NO

by

C. A. Bishop and J. W. Baird

Science Branch, Department of Fisheries and Oceans
P. O. Box 5667, St. John's, Newfoundland, Canada A1C 5X1

INTRODUCTION

The data presented in this document, in most cases, represents an update of that presented previously (NAFO Scientific Council Meeting June 1986 - See NAFO SCS Doc. 86/35). The methods and sources of data collection are the same and are not presented here in detail. Some tables are repeated for reference purposes but otherwise only new information will be presented.

Nominal catch and catch at age

Cod catches from Div. 3NO since 1977, along with corresponding TAC's, are as follows:

	1977	1978	1979	1980	1981	1982	1983	1984	1985	1986
TAC ('000 t)	30	15	25	26	26	17 ^b	17 ^b	26	33	33
Catch ('000 t)	18	15	28	20	24	32	29	27 ^a	35 ^a	

^aProvisional.

^bExcluded expected catches by Spain.

Landings by country for Div. 3NO are shown in Table 1 while Table 2 indicates catch information available by country, month, and gear for 1986 for the period January to June. Canadian landings for 1986 were obtained from the Department of Fisheries and Oceans Canada while that for other countries was obtained from estimates provided by Canadian surveillance personnel. The age composition for this first half catch, along with average weights and lengths at age (Table 4) was estimated using sampling data indicated in Table 3.

Survey data

Biomass estimates from Canadian research surveys by strata (Fig. 1) are shown in Tables 5 and 6 with mean number and mean weight per tow values in Table 7. Biomass estimates for Div. 30 originally presented in SCS Doc. 86/35, were based on preliminary data and were incorrectly calculated. The corrected data were substantially different from original estimates. Total biomass in both divisions showed a substantial increase from 1982 to 1984 with the stock biomass being somewhat stable from 1984 to 1986.

Estimates of abundance for non-sampled strata were once again obtained using analysis of variance of the ln catch per tow after the inclusion of 1986 survey data. Survey abundance estimates for the non-sampled strata for Div. 3N and 30 are shown in Tables 8 and 9. Mean number per tow estimates have declined since 1984 in Div. 3N but, have generally increased in recent years in Div. 30 with the exception of 1985. Mean number per tow estimates (Tables 10 and 11) show that the 1981 and 1982 year-classes were most abundant in 1986 and that there were significant numbers of fish of ages 10 and older in the population.

Recruitment index

Mean number per tow data from Canadian and USSR surveys were combined to provide a recruitment index for the stock using indices reported for ages 2 and 3 for year-classes 1974 to 1984. Data from the Canadian surveys was that obtained from mean number per tow data which had been adjusted for unsampled strata (Table 11) while that for the USSR surveys (year-classes 1974-82) was obtained from NAFO SCS Doc. 83/V1/16 and other unpublished data. Preliminary analyses indicated significant relationships between year-class abundances at age 2 and 3 within and between countries and as such combination was considered appropriate. Indices used (Table 12A) were first averaged over common year-classes (1974-79) and a new index obtained by scaling each to the average for the common year-classes. The arithmetic means of these scaled values (Table 12B) were used as a recruitment index. The relationship between this index and age 3 population abundance from a cohort at $F_t = 0.35$ (NAFO SCR Doc. 86/35) for year-classes from 1974-79 was significant with an $r^2 = 0.75$ but with a large positive intercept (Fig. 2).

Catch-effort data..

Catch and effort data from Canadian otter trawlers during the period January to June was added to that previously used for the period 1977-85 and analyzed using a multiplicative model (Table 13). Catch rates generally increased from 1977 to 1982-1983 (Table 14; Fig. 3) but have since declined.

Fishing mortality in 1985

In the previous assessment, attempts to determine F in 1985 from the relationship between average exploitable biomass (from cohort analysis) and catch-rate index were not successful mainly because of the small number of data points. It was stated that the discriminating power of a short data series could be significantly influenced by changes in the parameters and inclusion of additional years.

Data available since that time are not considered sufficient to permit new cohort analyses. The catch at age matrix for the January to June period was derived from landings of only 6361 t whereas landings will probably be in excess of 40,000 t. The catch rate data was similarly available for only the January to June period. The analysis using a multiplicative model does account for seasonality based on previous data and the catch rate index obtained indicated a general decline from 1982 to 1986.

The following relationships were considered with regard to surveys, CPUE, and cohort abundance and biomass to determine F in 1985. These were:

1. Age 5+ survey abundance vs age 5+ cohort abundance.
 2. Age 5+ survey abundance vs age 5+ cohort abundance (without 1984).
 3. Age 6+ survey abundance vs age 6+ cohort abundance.
 4. Age 6+ survey abundance vs age 6+ cohort abundance (without 1984).
 5. Total survey biomass vs cohort 3+ mid-year biomass.
 6. Total survey biomass vs cohort 3+ mid-year biomass (without 1984).
 7. CPUE vs cohort exploitable biomass.

Significant regression relationships were observed only for (4) and (5). In (4) the only significant relationship occurred at $F_t = 0.25$ (Table 15) for the range considered. R^2 was highest at this level but the residual in the last year was high and positive.

In (5) for a range of F's from 0.25 to 0.50 (Table 1b) all were significant except at 0.50. Highest R^2 occurred at lowest F but residuals were once again highest and positive at this F value.

Table 1. Catch (metric tons) of cod in NAFO Divisions 3NO.
