ABSTRACT

Results from the 1983-1988 trawl surveys indicate some reduction in witch stocks in Div. 3L for 3 recent years and stock stability in Divs. 3NO which are confirmed by a constant length composition of fishes from catches.

INTRODUCTION

At present, stock of witch as well as of other commercial objects is estimated in trawl surveys. A complete coverage of a whole range of fish vertical distribution during survey is necessary to obtain the more precise estimate for stock. In Canadian scientists opinion the data obtained during surveys are insufficient for stock precise estimation since the surveys were, as a rule, conducted at the depth to 360 m (Bowering, 1987, 1988). They also regard the data available on commercial statistics to be insufficient for determining the fishing mortality (Bowering, 1988).

An attempt to estimate witch stock according to the results from Soviet trawl surveys conducted at the depths to 730 m in Divs. 3LNO in 1983-1988 was undertaken in the paper.

MATERIAL AND METHODS

Since 1983 Soviet stratified-random trawl surveys have been carried out according to the available methods

(Doubleday, 1981). Since 1984 a haul duration was half-hour and prior to this year it was 1 hour. Assuming that catch size depends directly on haul duration, the mean catches results for 1983 given in Tables were reduced to half-hour hauls.

Mean (for each stratum and Division) number (indiv.) and fish weight (kg) in catch per 30 minutes of trawling over the swept area of 0.0135 mile² were taken as the indices for biomass and abundance. Fish measurements by sex were presented as plots of length frequencies in percentage of males and females, respectively.

RESULTS AND DISCUSSION

Tables 1, 2 and 3 present the results for witch stock estimation by strata in Divs. 3L, 3N and 3O. Fish biomass made up on the average about 50% at the depths over 360 m in Div. 3N and about 4 and 31% - in Divs. 3O and 3L, respectively. From 1983 to 1988 some increase in biomass at the depths over 360 m was observed in Divs. 3L and 3N. This agrees with Bowering's hypotheses (Bowering, 1988) that variations in the previous estimates for witch biomass were related to changes in fish distribution.

Data on fish abundance and biomass given in Table 4 indicate a possible stability of stock in Divs. 3N and 3O and a reduction in stock in Div. 3L for recent 3 years.

Analysis of fish length composition from catches taken in Divs. 3L, 3N and 3O was made for 1982-1988 (Fig. 1, 2 and 3). Similarity in witch length composition confirms the hypothesis of stable stock level on the Grand Newfoundland Bank every year.
