Assessment of the Cod Stock in Div. 3NO and Div. 3KL

from the 1989 Trawl-Acoustic Survey

by

A. Yu. Bulatova

Polar Research Institute of Marine Fisheries and Oceanography (PINRO)
6 Knipovich Street, 183763, Murmansk, USSR

ABSTRACT

The paper contains the estimates of the cod stocks in Divs. 3NO and 3KL from the trawl-acoustic survey made in March-May 1989.

In Divs. 3NO the cod stock gradually goes down due to poor recruitment from the 1983-1988 yearclasses. The trawl-acoustic survey estimated the abundance at 18.3×10^6 fish and the biomass at 107.5×10^3 t.

The Labrador cod stock (Divs. 3KL) was close to the 1988 level and higher than the 1977-1989 average. The estimated abundance was 651.7×10^6 fish, the biomass - 944.7×10^3 t.

INTRODUCTION

For a number of years PINRO has been conducting surveys in NAFO Subarea 3 to monitor the status of commercial fish stocks.

A regular trawl-acoustic survey was made in March-May 1989 by RV "Persey-III". The objective of the paper is to analyse the results obtained, evaluate the abundance and biomass of cod in Divs. 3NO & 3KL in 1989 as compared to the same data for 1977-1988.

MATERIALS & METHODS

The random-stratified trawl survey used the methodology developed by Doubleday (1981) and was made together with an acoustic survey. The acoustic observations allowed estimation of the cod stock part distributed above 1 m from the bottom and out of reach for bottom trawl. Pelagic part of the stock was estimated according to the methodology described by Mamylov V.S. (1988).

The abundance and biomass indices estimated from the trawl-acoustic survey were brought together to derive total values by strata and Division. The strata with no cod in catches were not included into the calculations.

RESULTS

Divisions 3NO. In March-April 1989 environmental and feeding conditions in the southern Grand Bank were not favourable for formation of cod concentrations. During this period the near-bottom temperatures over the greater part of the area were 0.5-1.5°C below normal and 0.3-1.0°C colder than in 1988. The most considerable anomalies occurred on the eastern slope in the Main Branch of the Labrador Current. The frontal zones were ill-pronounced. No spawning capelin concentrations which make for concentration of cod were observed.

Under such conditions the cod were sparse (Fig. 1). At depths 55-270 m the average catches ranged from 3 to 10 fish in different strata, and at depths greater than 270 m the average catches were up to 16-28 fish per 30 min. tow. Larger fish, the catches of which averaged 40 to 120 kg by strata, occurred in large shallow strata in Div. 3N; on the slopes deeper than 100 m the average catches dropped to 1-16 kg. This seems to account for a relatively high estimate of the biomass at extremely low fish abundance in Div. 3N.

In 1989 the cod abundance as estimated from the trawl survey decreased by a factor of 4, and the biomass by a factor of 1.5 compared to 1988 (Tables 1,2,3). Both estimates were below the 1977-1989 average level (Table 1).

The cod abundance and biomass from the trawl-acoustic survey were 18.3×10^6 fish and 107.5×10^3 t, respectively, which was also below the values from the 1987-1988 surveys (Table 4).

The southern Newfoundland cod stock values could probably have been somewhat higher if estimated later in the year. Some fish tagged in April near Virgin Rocks migrated to the southern Grand Bank in May-July: of 44 recaptured fish 27% were taken in Divs. 3NO in May-July and 38% - from May to December.

Canadian trawl survey data (Baird and Bishop 1989) also indicated a decrease in abundance (by a factor of 1.5) and in biomass (by a factor of 1.3) of cod in Divs. 3NO though it is not so large as by the USSR data.

Poor recruitment to the stock from the 1983-1988 yearclasses (Table 5) seems to be the major reason of the decrease in the southern Newfoundland cod stock. In 1989 there occurred an increase in the average length and age of fish taken in research

tows (Tables 6,7). Fish of 27 to 38 cm and 63 to 77 cm in length at age 3 to 4 and 7 to 8 from the 1986, 1985, 1982, and 1981 year-classes made the bulk of the catches. The mature fish in the stock were 28%.

Divisions 3KL. In May the main cod concentrations in Div. 3L were northwest of Virgin Rocks (the peak catch - 800 kg) and in the northern part of the slope at depths 200-240 m (the peak catch - 300 kg). In Div. 3K a higher density of concentrations was observed at depths 320-360 m on the western and eastern slopes of a deepwater trench (Fig.2). A clearly pronounced frontal zone on the western slope of the trench prevented the cod from migrating towards the coast. The average catch within the 300-400 m depth range was 420 kg (peak catches were 1 to 3 t) at smaller and greater depths the catches dropped to 17-25 kg on the average by strata.

Judging by the age and length composition of fish, the Labrador cod stock status is relatively stable (Tables 6,7). Fish of 36 to 44 cm and 54 to 65 cm in length at age 3 to 8 were predominant in the catches taken in Div. 3L. The catches in Div. 3K mainly consisted of 48 to 62 cm fish at age 5 to 7 from the 1984-1982 yearclasses.

Comparison of the 1988 and 1989 trawl survey data shows a decrease in abundance in Divs. 3KL by 1989 (from 395.6×10^6 down to 353.2×10^6 fish) and an increase in biomass (from 490.6×10^3 up to 547.7×10^3 t) (Tables 8,9). In general, the stock was close to the 1988 level and above the 1977-1989 average. The trawl-acoustically estimated abundance and biomass were 651.7×10^6 fish and 944.7×10^3 t, respectively (Table 4).

CONCLUSION

The decrease in the southern Newfoundland cod stock (Divs. 3NO) seems to be associated with the poor recruitment to the stock from the 1983-1988 yearclasses. With slightly smaller, than in 1988, abundance but higher biomass the Labrador cod stock in 1989 remained at an above-average level.
