SCIENTIFIC COUNCIL MEETING - JUNE 1991

The shrimp fishery in NAFO Subarea 1 in 1990

by

D. M. Carlsson and P. Kanneworff

Greenland Fisheries Research Institute,
Tagensvej 135, DK-2200 København N. Danmark.

INTRODUCTION

The scientific advice for the offshore catch of shrimp in NAFO Subareas 0 and 1 (not including Subarea 1 north of 71°N) was 50,000 tons for 1990. The effective TAC for offshore Subarea 1 - in the area for which advice was given - was set by the Greenland Home Rule Authorities at 37,725 tons, including a Greenland allocation of 36,725 tons. Greenland trawlers above 75 GRT reported a total catch in the Subarea of 41,962 tons, including 2,121 tons taken north of the area considered by STACFIS. Total catches of smaller vessels are estimated to about 20,500 tons, of which about 5,500 tons were taken in the offshore area (preliminary figures).

Until 1986 only logbooks from the fishery of nine trawlers owned by the Greenland Home Rule Administration were available to the Greenland Fisheries Research Institute (GF). Since 1986 logbooks have been compulsory for all vessels above 50 GRT fishing in the offshore area. For 1990 logbooks available to GF cover about 159,500 hours of trawling and a total catch of about 49,000 tons of shrimp in Subarea 1. The logbook data base has been used to estimate standardized effort in catch rate calculations.

The present paper updates earlier information on the geographical distribution, catch rates and by-catches in the offshore Subarea 1 shrimp fishery. Also, results from analysis of samples from the commercial shrimp fishery is presented.

MATERIAL AND METHODS

Based on the compulsory weekly reportings to Greenland authorities by all vessels above 75 GRT total catches and numbers of vessels in the shrimp fishery in NAFO Subarea 1 in 1990 were compiled by nation and month.

Logbook data were analyzed to show the yearly and monthly distribution of catches, fishing effort and mean catch-rates.

Mean catch-rate indices for seven trawlers for the July-September period have been used since 1976 to reflect the state of the shrimp stock in Div. 1B. This index covered only a certain part of the year, while changes in availability inside years might occur, and therefore a multiple regression analysis was carried out in 1990 on the data for the seven trawlers from 1976 to 1989 to obtain an index which would be an improved representation of the performance of the fleet (Lassen and Carlsson, 1990). Most of these vessels have now been taken out of the fishery, so neither of these indices can be continued. Instead a new standardized index based on a larger part of the fleet and taking into account non-reported discard of shrimp has been developed as presented elsewhere (Carlsson and Lassen, 1991).

Shrimp samples from the commercial shrimp fishery were measured to nearest .1 mm carapace length and pooled in .5 mm length groups by division and quarter to show overall size distribution of commercial catches.

RESULTS AND DISCUSSION

Reported catches in 1990

Table 1 shows catches by division, nation and month in offshore Subarea 1 in 1990 as reported by vessels above 75 GRT, and Table 2 the numbers of reporting vessels. The figures for Greenland include catches in the offshore fishery north of 71°N, but these catches have declined steadily since 1986 (about 11,000 tons) to about 2,000 tons in 1990.

The shrimp landings from Subarea 1 in 1990 by smaller Greenland vessels (below 75 GRT) are about 20,500 tons (preliminary figure), of which about 15,000 tons are estimated to be inshore catches.

The preliminary total nominal shrimp catch in Subarea 1 was about 63,500 tons in 1990, which is about 2,500 tons more than in 1989.

Geographical distribution of the offshore fishery

Figure 1 shows the distribution of total catches (in tons per statistical unit) in 1990 as recorded in the logbook data base from Greenland trawlers. As in earlier years the fishery concentrated in Sukkertoppen Deep (64°-64°30'N), Holsteinsborg Deep (around 66°30'N), and in the northern and western slopes of Store Hellefiske Bank and Disko Bank. Some catches were also taken in the southernmost grounds in the Northwest Greenland area. Higher catches than normal were taken in Sukkertoppen Deep.

Since 1987 there has been some yearly changes in the distribution of the fishery between divisions as illustrated by Table 3, which shows effort (in hours) by year and division from 1987 to 1990 in the logbook data for greenland trawlers (>50 GRT). Table 4 shows distribution of catches in the same data (the figures are not directly comparable to reported catches in Table 1, as these are only from vessels above 75 GRT). The tables show a shift in the fishery in recent years with more effort being spent in Div. 1C and 1D.

Figure 2 shows the monthly distribution of mean catch-rates and effort (numbers of hours trawled) from January through December 1990. As has been the case in several years (1983, 84 and 87-89) ice hampered the access to the fishing grounds west and north of the Store Hellefiske Bank area in the beginning of the year. From January to April only the grounds in Sukkertoppen Deep and Holsteinsborg Deep were open, and not until May was it possible to access the grounds north of Store Hellefiske Bank. During the rest of the year the fishery was widespread.

The fishery north of 71°N took place from June to December

The area between 68°30'N and 71°N west of 58°W is a new regulatory area established in 1989. Although the area is south of 71°N, Greenland authorities do not consider it part of the area for which STACFIS advises. About 2,250 tons were reported from this area in 1990.

Biological samples

Data on numbers of shrimp by length in shrimp samples from the commercial fishery in Subarea 1 pooled by division and quarter are given in Table 5 and Fig. 3. Samples from Div. 1A in the third quarter show a dominant peak of female shrimp around 27 mm carapace length and a smaller group of males around 21 mm. Samples from Div. 1B all show dominant peaks around 20 mm and 24.5 mm, the first peak representing males and the second females. There are indications of growth of males by the progression of the peak from 19.5 mm in the second quarter to 21 mm in the fourth quarter. The female group in the second quarter has two peaks, of which the first peak around 23.5 mm may indicate primiparous females, that are included in the general female group in third and fourth quarter after spawning.

CONCLUSIONS

The nominal offshore catch of shrimp in NAFO Subarea 1 is estimated to be about 63,500 tons in 1990, including about 2,000 tons from the area north of 71°N.

As in earlier years, but different from 1985 and 1986, ice hampered the access to the important shrimp fishing grounds on the slopes of Store Hellefiske Bank in spring time.

A significant shift in the fishery took place in 1989 and 1990, larger parts of the catches being taken in Div. 1C and 1D compared to the years before.

Shrimp samples from the commercial fishery in Div. 1A and 1B show one dominant male peak and one dominant female peak. Growth is indicated for the male group from second quarter throughout the year and for primiparous females between the second and the third quarter.
