Results of Investigations of Roundnose Grenadier  
in NAFO Subarea 0, 2 and Div. 3K in 1971-92

by

ABSTRACT

The paper presents distribution of roundnose grenadier by depth, as well as age and length composition, sex ratio of fish in catches. Percentage of grenadier, Greenland halibut and redfish in catch from different depth is given. Mean length of roundnose grenadier was estimated to be 45.3 cm and mean age - 7.5 by the results of 1992 survey, that was lower than those in 1991. A sharp increase in fish mean length and in relative female number with depth was observed to be similar to that of recent years. Roundnose grenadier percentage in catches in 1988-1992 was much lower than in 1971-1977, while their catches decreased more than 10 times for this period. Trawl-acoustic survey for 1992 indicated a lack of grenadier concentrations at depth of traditional fishing.

INTRODUCTION

In the Northwest Atlantic, the total catch of grenadier (*Coryphaenoides rupestris*) have been accounted for tens thousands tons per year up to 1978. The total catch have been reduced sharply since 1979. Both catch and catch per unit effort were observed to decrease gradually in subsequent years. It could not be explained by overfishing since the catch was negligible. Data from trawl-acoustic surveys, conducted annually in autumn-winter on the Baffin Land, Labrador and Grand Newfoundland bank, indicate nearly a lack of grenadier fishing concentrations in the depth range from 500-1500 m. The aim of the paper is to analyse the results of 1992 survey and to compare them with those of recent years in order to study the reasons for catch decline.

MATERIAL AND METHODS

The results of surveys for bottom fish stocks assessment annually conducted in autumn-winter are used in the paper. Roundnose grenadier catches per hour towing by bottom trawl by 100 m depth intervals are presented. Survey methods were given in details previously (Bulatova, Chumakov, 1986). Tables show the age composition for 1983-1992, have obtained by length frequencies calculation using the combined age-length key for Div. 3K for 1969-1992. Age composition was estimated by Subareas 0 and 2 separately by calculation of an age sample taken from Div. 2GH in 1992, and that for Div. 3K - by an age sample taken from the same Division in 1992. Percentage series and length frequencies in Figures, as well as catch data from different depths for 1971-1992, presented in the Table, have been smoothed by the formula:

$$B = \frac{a+2b+c}{4};$$

where a, b, c - preceding, middle and subsequent members in the series;  
B - calculated member.

RESULTS AND DISCUSSION

Biological characteristics and distribution of roundnose grenadier by area and by depth in 1992 were studied during trawl survey for bottom fish assessment by RV "Kapitan Shaitanov" in Divs. 3K, 0B, 2G, 2H and in the Flemish Pass area in the depth range 190-1460 m.

It is known, that in recent years in the Flemish Pass area deepwater fishing for Greenland halibut have been carried out by Spanish and Portuguese vessels. From 17 to 20 October 1992, total of 9 towings within the depth range 900 - 1150 m were done to study Greenland halibut and grenadier distribution in this area. Catches per hour towing were ranged from 20 to 180 kg. Greenland halibut

accounted for 40-90%, roundnose grenadier - 15-20%, with wolffish and roughhead grenadier constituting the by-catch remainder.

From 22 to 27 October 1992 in Div. 3K (traditional area for grenadier fishing), a series of bottom towings were done at every 100 m interval in the range from 500 to 1460 m to study the vertical distribution of bottom fish. No grenadier were found at depths above 800 m, while it was accounted for 65-68% in catches from below 800 m level (Table 1). Distributions by depths for the three main species -Greenland halibut, roundnose grenadier and redfish (*Sebastes marinus*) - were similar to those in 1991 (Savvatimsky, 1992), while catches were lower. Percentage of Greenland halibut, roundnose grenadier and roughhead grenadier (*Macrourus berglax*) in catches from maximum depth of 1401-1460 m was estimated as follows: 38, 84% and 13%, respectively. At lower depths, roundnose grenadier by-catch was estimated to be 1-3%. The remainder of the by-catch was estimated at 7-9% and consisted of northern wolffish (*Anarhichas denticulatus*) mainly at depths between 500-900 m.

Trawl survey in Div. 0B was conducted from 25 to 29 November 1992 at depth range 500-1300 m. As well as in recent years, roundnose grenadier occurred as a negligible by-catch in Greenland halibut fishing. Maximum catch of grenadier have totalled 15 kg.

Trawl survey in Div. 2G and 2H was carried out from 30 November to 15 December 1992 at depth range 500-1400 m. The area between 58° and 59°N was not surveyed because of hard ice conditions. Grenadier occurred in catches from between 701-800 m and 901-1000 m and dominated the catches below the latter, while catches were not substantial. On the whole, catches in all Divisions were lower than those in 1991 (Table 2).

Therefore, trawl survey showed that no grenadier concentrations occurred at traditional fishing depths in all surveyed Divisions in 1992.

In 1992 in Divs. 0B, 2GH and 3K, the mean length of grenadier in catches was estimated to be 45.3 cm (Table 3), with mean age of 7.5, that was lower than those in 1991. Length frequencies of catches by every Division are presented in Table 5. Mean length of fish in catches was estimated as follows: 41.1 cm in Subarea 0, 42.8 cm in Subarea 2, 49.8 cm in Div. 3K, while the mean age was 7.8, 8.2 and 8.5, respectively (Table 6). These parameters depend on depths. As in recent years, a sharp increase in mean length of both males and females and in relative females number of grenadier with depth was noted in all Divisions (Table 7, Fig.1). These variations have been investigated by trawl surveys during series of years (Savvatimsky, 1989, 1990, 1991) and seemed to be a pattern.

Age-length composition and relative number of grenadier in catches are closely connected with their vertical distributions. The percentage of grenadier in catches in 1988-1992 was much lower than that in 1971-1977 (Fig. 2), and their catches at traditional depths of fishery decreased more than 10 times (Table 8). It could not be explained by overfishing, since total catch in 1975-1979 was negligible, and catch per effort decreased after total catch decline. Decrease in grenadier abundance, caused by variations in habitat conditions, as well as migration of concentrations to deeper layers could be considered as probable reasons for a lack of grenadier concentrations at traditional catch depths.
