SCIENTIFIC COUNCIL MEETING - JUNE 1993

The Commercial Shrimp Fishery in Denmark Strait
in 1992 and Early 1993

by

Dan M. Carlsson & Per Kanneworff

Greenland Fisheries Research Institute, Tagensvej 135, 1,
DK-2200 Copenhagen N., Denmark

INTRODUCTION

In 1991 STACFIS recommended that the total allowable catch of shrimp in the Denmark Strait in 1992 should be reduced to 8,000 tons. In the Greenland zone the effective TAC was set to 13,000 tons, while the total catch reported from this area was 5,658 tons. Greenland vessels accounted for approximately 2,000 tons.

The fishery was carried out from January to May and from September to December, most effort being spent in the first period. Approximately 3,800 tons of shrimp were reported from the first period and approximately 1,800 tons from the second period. In 1993 from January through May a catch of about 4,500 tons has been reported.

Logbooks from all the 19 Greenland vessels and from one Danish and 10 Faroese vessels fishing at East Greenland in 1992 have been available to the Greenland Fisheries Research Institute. The logbooks cover about 52% of the total catches in the Greenland economic zone.

The present paper updates information given by Carlsson & Kanneworff (1992) on catches and analysis of commercial fishery data.

MATERIALS AND METHODS

Total catches and number of vessels fishing in the Greenland zone were compiled by nation and month based on the compulsory weekly reporting to Greenland authorities by all vessels above 75 GRT (smaller vessels are not fishing in this area).

Logbook data were analysed to show the overall distribution of catches by year and of effort and catch-rates by month. Monthly mean catch-rates from 1980 to early 1993 were calculated from available logbook data.

Based on logbook data from 27 Greenland trawlers a multiplicative model was run using the SAS multiple regression procedures to calculate standardized annual catch rate indices for the total catch, and for shrimp larger than 8.5 g to avoid the influence of unreported discard. The method is described in Carlsson and Lassen, 1991. Catch of large shrimp and total catch were aggregated by vessel, month and year. All cells with less than 10 hours of effort or with 10% or more of the catch not being sorted by shrimp size were excluded to avoid the influence of cells with few hauls and of non-sorted catch. Out of a possible 1944 cells this brought the number of cells down to 595, of which further 10 were removed as marked outliers. Although some improvement in r-square values could be obtained by including interactions in the model, the final runs were done with the simple model.

Shrimp samples from the commercial fishery in February 1992 were analysed for size composition of catches. The samples were taken by observers in a project to estimate discards in the commercial fishery (Siegstad, 1993).

RESULTS AND DISCUSSION

Reported catches in 1992 and 1993.

Tables 1a and 1b show reported catches in the Greenland zone by nation and month, and Tables 2a and 2b the corresponding total numbers of reporting vessels for the years 1992 and 1993 (January to April), respectively. The catch figures should be considered minimum figures due to unreported discard of shrimp (Siegstad, 1993).

The seasonal distribution of the fishery in 1992 was similar to previous years in that little or no fishing took place in the summer period (June to September). Highest catches were taken in January to March and in November and December. About 32% of the reported catches were taken in the second half of the year.

For January-May 1993 a total catch of approximately 4,500 tons has been reported (preliminary figure), which is less than in the same period in 1991 (approx. 6,000 tons), but more than in January to May 1992 (3,800 tons). In 1993, however, observers have been placed onboard most of the vessels fishing in Greenland zone in Denmark Strait, and hence the amount of unreported discard may have been significantly reduced. A total of 47 vessels participated in the spring fishery in 1993 (Table 2b).

To reduce the amount of unreported discard in the shrimp fishery Greenland authorities have in 1993 implemented an observers programme with two observers onboard each vessel (> 80 GRT). Also, a minimum mesh size of 55 mm (stretched) in the cod-end has been introduced from April 1, 1993.

Geographical distribution of the fishery.

Fig. 1 shows the distribution of total catches by Greenland vessels in 1992 and Fig. 2 the monthly distribution of CPUE and effort from January 1992 to April 1993 by statistical rectangle.

The geographical distribution of catches in 1992 (Fig. 1) was similar to that of 1990 and 1991 (Carlsson and Kanneff, 1991, 1992). In previous years it changed substantially between years, depending primarily on variations in ice coverage and the distribution of shrimp over the area (Carlsson and Kanneff, 1990), but in the last three years it concentrated in the same areas between $65^{\circ}30'$ and $67^{\circ}N$ and 30° and $32^{\circ}W$.

In 1990 the northern part of the so-called 'redfish-box' southwest of the traditionally most important shrimp fishing areas was opened to the shrimp fishery. The 'redfish-box' was originally pointed out in the early eighties by the ICES Redfish Working Group as an important nursery area for especially redfish and was as such closed for trawling. The area follows the east coast of Greenland from $63^{\circ}30'N$. to $67^{\circ}N$. The opening in 1990 resulted in temporarily high catch rates of shrimp and at the same time very little by-catch of redfish. Since then, however, catches in the area have been small. The total 'redfish-box' was opened for the shrimp fishery by Greenland authorities in early 1993, and about 50 tons of shrimp was fished south of $65^{\circ}N$ in January to March 1993.

The monthly distribution of the fishery in 1992 (Fig. 2) and in January to March 1993 (Fig. 3) was very similar to that of 1991 (Carlsson and Kanneff 1992). In the spring period of 1992 and again in December 1992 to March 1993 the fishery concentrated in the central parts of the fishing grounds, while in October and November it was more widespread with low catch rates. Catch rates in 1993 in the former 'redfish-box' south of $65^{\circ}N$ (Fig. 3) were generally low.

CPUE and effort.

Monthly and semi-annual mean catch rates in the Greenland fishery in the main fishing area in Denmark Strait are shown in Table 4. While catch rates are fluctuating between months, there is a evident declining trend in mean catch rates for the January to June period from 1988 to 1993. For the July-December period mean catch rates decrease from 1988 to 1989 and show a slight increasing trend from 1990 to 1992. Monthly and semi-annual mean catch rates in the Danish and the Faroese fishery in Denmark Strait (Tables 5 and 6) show a similar decreasing trend in the January-June period and stability in the July to December period over the last three to four years.

Figure 4 shows the monthly mean catch rates in the Greenland fishery from 1986 to April 1993. The high peak catch rates found in the winter-spring fishery in earlier years are not present since 1991, and catch rates appear more stable over the fishing periods.

Standardized CPUE-index.

The results of the multiple regression analysis to standardize catch rates of large shrimp (Table 9) show that the model explains 68% of the total variation with all three variables highly significant. T-values suggest that for all years from 1987 to 1991 catch rates were significantly higher than in 1992. Histogram, box- and probit plots of the residuals (Fig. 5) suggest that the residuals are normally distributed without marked outliers.

Results of the same model run for the total catch (not shown here) were similar to the results for large shrimp catch. Because of few cells/little effort spent in June, July and August (Tables 7 and 8) the model was run omitting these month, but this had no effect to the results.

Calculated annual cpue-indices for large shrimp and total catch based on results from the regression analysis are shown in Fig. 6. Except for 1989-1990 the indices show a significantly declining trend as indicated in raw catch rates (Fig. 4).

Biological samples.

Commercial shrimp samples from the fishery in 1992 were not sorted by sexual characteristics. Fig. 8 shows length frequency diagrams for pooled samples from February 1992 by statistical units used by Iceland (Fig. 7), and Table 10 gives the numbers of shrimp by length group in the samples. The samples show considerable variation in size composition between areas. In all samples a peak is found at 26 mm carapace length. As indicated by results from the trawl survey in 1992 (Carlsson and Kanneff, 1993) this size group may consist of males and (at that time of the year) primiparous females. Smaller size groups of males are almost absent except for the southern areas (unit 580 and 581), where peaks are found at 22 and 24 mm carapace length. A variety of size groups with peaks between 28 and 34 mm is found in all samples. The catches presented by the samples (Table 10) suggest that the density of shrimp in February 1992 was highest in the southermost areas (unit 580 and 581), with a dominating group of females at 30 mm carapace length.

CONCLUSIONS

Reported catches of shrimp in 1992 from the Greenland part of Denmark Strait totalled 5,658 tons, the lowest catch since 1983 in that area. 52 vessels participated in the fishery. The mean catch per vessel was about 110 tons in 1992, compared to 170 tons in 1991 and about 150 tons in 1989 and 1990. The fishery took place from January to May and from September to December. 68% of the catches were taken in the first half of the year.

From January to May 1993 a catch of about 4,500 tons has been reported, taken by 47 vessels.

As in 1990 and 1991 the fishery in 1992 was concentrated in the area between 65°30' and 67°N and 30° and 32°W, different from previous years, when the fishery was more widespread. In 1993, after the opening of an area hitherto closed for the fishery, some fishing occurred southwest of the traditional area.

Semiannual mean catch rates for Greenland, Danish, and Faroese vessels show a declining trend in the January-June period from 1988 to 1993 and stability in the July-December period in the last three to four years.

Standardized catch rate indices for catch of large shrimp and total catch of 27 Greenland trawlers show a declining trend from 1987 to 1992, except for stability between 1989 and 1990.

Biological samples from the commercial fishery in February 1992 show a variety of modes, smaller males however being absent except for the southern part of the fishing area, where density of shrimp was highest, and a female component at 30 mm carapace length dominated the samples.
