Sea Hunting Statistics for Greenland 1993 and 1994, According to a New System
of Collecting Information, Compared to the Previous Lists-of-Game

by

ABSTRACT

In 1992 a new system of collecting hunting statistics for Greenland was introduced. The system is linked to renewal of hunting licences, and the individual hunters are obliged to fill out forms with their own results during the preceding year. Results are now available for 1993 and the first nine months of 1994. They are presented in the following tables, including the authors' estimate for the three last months of 1994. For comparison a summary of previous catch statistics based on the so-called Lists-of-Game, and of seal skin purchase 1971-1992, is added.

According to the new hunting statistics, the catch of harp seal was at a much higher level in 1993-94 than reported or estimated in the early 1980s. The catches of ringed and hooded seals were, however, not significant different from the levels estimated previously. This might indicate that the increase in the catch of harp seal is real, but the reliability of the new system needs further investigation.

COLLECTION AND HANDLING OF DATA

The new system of collecting hunting statistics in Greenland

In 1992 it was decided to introduce a new system of collecting hunting statistics in Greenland, and the system came into force counting from January 1993 (Anon. 1992, 1993a. 1993b). The system is linked to the issuing of hunting licences, of which two categories exist: one for full-time hunters, and another for part-time hunters. Both categories have to pay a small fee for renewal of the licence, and are obliged to report on their results during the preceding year. The licence year runs from October to September, for which reason results are now only

available for the year 1993 and the first nine months of 1994. In 1993, about 9,500 licenses were issued (4,100 full-time and 5,400 part-time), and 7,671 reports were received (3,403 from full-time and 4,268 from part-time hunters). A number of licence holders reported "no catch", and in 1994 only about 7,200 licenses were issued (3,100 full-time and 4,100 part-time). For that year 6,293 reports (2,772 and 3,521, respectively) were received (by May 1995). All Danish citizens (and foreigners having stayed more than two years in Greenland) can apply for a part-time licence and will get one if the conditions are met (paying the fee, and reporting), but for obtaining the status of full-time hunter the approval by the local municipal authorities is required.

When the licence is issued, the hunter receives a small booklet for noting his catch results. It contains a form for each month, and a summary form for the whole year (a sample is shown in the Appendix, form B). The list of species to be reported include marine mammals (except large whales), some terrestrial mammals, and several game birds, altogether 21 species (see Appendix).

The old system: The 'Lists-of-Game'

Since the late 19th century hunting statistics have been collected in Greenland through the so-called Lists-of-Game. The principle in that system was that a person was appointed at each settlement to keep account of the hunting results of all the hunters at that settlement, and report to the central authorities on forms ('Lists-of-Game'), one for each individual engaged in hunting (Rosendahl 1961, Kapel 1975, 1986, 1991, 1993).

The Lists-of-Game never functioned completely satisfactory for all settlements in Greenland. For shorter or longer periods reports were not received from a number of localities, or were clearly incomplete. For that reason, estimates of "non-reported catch" were given on a settlement by settlement basis, and added up by districts in the published summaries. These estimates constituted an increasing part of the estimated total catch during the 1970s and early 1980s, for which reason some users took the position that the statistics became increasingly unreliable, whereas others believed that the Lists-of-Game were still giving a picture of trends although they were not presenting exact but rather minimum figures (Kapel 1991). The basis for the estimates of non-reported catch at a given settlement were the trade statistics mentioned below, various sources of local information, and comparison with reports from previous years and adjacent settlements in the same year.

In 1984 the responsibility for handling and publishing the summaries of the Lists-of-Game was transferred from the Ministry for Greenland to the Statistical Office of the Greenland Home Rule Authorities. The material for 1984 and 1985 was treated in the same way as in previous years (i.e. including estimates of non-reported catch), but never published. For 1986 and 1987 the material was still collected, but no estimate of non-reported catch was attempted. After that, the old system was discontinued and catch statistics for Greenland are not available for the years 1988 to 1992, when the above-mentioned new system was introduced.

The number of species reported through the Lists-of-Game has varied over time, but since 1971 they included all pinniped and cetacean species, polar bear and caribou, but not other land mammals or birds (see Annex).

Trade (purchase) statistics

Trade statistics have an even longer history in Greenland, dating back to the 18th Century. They give information on a number of hunting products, including oil (blubber) and seal skin. Locally treated (washed but raw) seal skins were previously purchased by the local manager of KGH (the Royal Greenland Trade Department), sorted by species, quality and size category, and shipped to Denmark where they were either tanned or sold raw on annual auctions. There was no limitation in the number of skins that could be purchased locally, and the purchase statistics could therefore be used for comparison with information from the catch statistics.

The relation between the catch of seals and the purchase of skins varied from one locality to another, depending on the local use or interest in making an income from hunting, but the two sets of statistics often showed similar trends.

In recent years, however, most seal skins have been sent to South Greenland to be processed at the Home Rule owned tannery there, and due to market constraints and economical considerations the trading policy has changed, including suspension of the purchase of some seal skin categories (e.g. those of large harp seals). The present trade statistics for seal skins are thus no longer immediately comparable with the previous ones, or with the hunting statistics.

REPORTED OR ESTIMATED CATCH OF SEALS IN 1993 AND 1994

The results of the new system of collecting hunting statistics in Greenland is shown for the three most important seal species in the following tables. Tables 2-7 present the information on the catch of harp, ringed and hooded seals by month and region or district for 1993; for 1994 when only data from January to September are available, we give a preliminary estimate of the expected catch during the following three months, and in the whole year. Table 8 (and the accompanying Figure) presents catch and purchase statistics for the periods 1971-1987 and 1971-1992, respectively, and Table 1 compare catch statistics for 1983 and 1993-1994.

Harp seal

Tables 2, 4 and 6 give the data on the reported catch of harp seals in 1993 and 1994. According to this information 55,683 harp seals were caught in Greenland in 1993, of which just over 50 % (28,290) were reported as young or immature seals ("blåsider", i.e. spotted animals: beaters and bedlamers). During the first nine months of 1994, the reported catch was 37,824 (18,987 spotted) harp seals; the total catch in 1994 is tentatively estimated at about 47,000. This catch level is the highest ever recorded for Greenland: Based on information from the Lists-of-Game and trends in purchase statistics, the catch of harp seals in 1992 was previously estimated to be of the order 25,000 (Table 8, Kapel 1993), the same level as in the late 1940s (Kapel 1986).

The regional and seasonal distribution of the catches of harp seal (Table 4 and 6) is in general agreement with previous data from the Lists-of-Game (Rosendahl 1991, Kapel 1975), and with recent information from tag recoveries (Kapel, this meeting, SEA-59). It is worth noting that this most recent catch information indicates that quite a few harp seals spend the winter (December-March) in Greenland, not only immature animals but also many older seals ("sortsider", saddlebacks).

Hooded seal

According to the new statistics, the catch of hooded seals was 6,906 in 1993 and 6,772 in the first nine months of 1994 (estimated total about 7,670; Tables 1 and 3). This level is slightly higher than the catches reported or estimated for the late 1970s and early 1987, but not significantly so (Table 8).

The regional and seasonal distribution of the hooded seal catches (Tables 5 and 7) agree fairly well with previous information (Rosendahl 1961, Kapel 1975), although the catch level in the southernmost part of West Greenland (South Greenland = Narsaq, Qaqortoq and Nanortalik districts) that used to be the "classical" area for hooded seal hunting in spring is now apparently not as dominant compared to the hunting in the region "Southwest Greenland" (Paamiut-Sisimiut). A strange feature is the very large catch of hooded seal reported from Thule district in June (May-July) 1994; this contrasts previous information and needs checking. If correct, it indicates presence of hooded seals far north in the Baffin Bay region at a time, when they are moulting.

As in the case of harp seal, the new statistical information also indicates that a fair number of hooded seals spend the winter months in Greenland waters.

Ringed seal

Tables 1, 3, 5 and 7 show that the catches of ringed seals reported for 1993 (75,644) and 1994 (estimated total 67,040) are within the range of the total annual catch of ringed seals in Greenland reported or estimated during the period 1971–1985 (59,000–97,000 ; Table 8).

Comparison of the regional distribution of estimated ringed seal catches in 1983 with those in 1993 and 1994 (Table 1) indicates, however, significant differences: For Thule, Ammassalik and Scoresbysund the catch levels estimated for 1983 are significantly higher than those reported for 1993 and 1994, whereas the 1983 levels estimated for several other districts (particularly in Central West Greenland) were significantly lower than reported in 1993 and 1994.

PRELIMINARY COMMENTS ON THE NEW CATCH DATA

The results of the new system of collecting hunting statistics in Greenland have only very recently become available to the authors, so a thorough analysis and evaluation has not been possible. The following comments should, therefore, be considered preliminary.

When comparing the old and new system of collecting hunting statistics two features should be noted: the difference in approach and the reporting intensity.

The Lists-of-Game represented an "indirect" reporting procedure: One person reporting the hunting results of everyone at a given settlement. As long as the settlements were small, this old system was feasible, and it seemed to work well for a number of years at many localities. But when the size of a settlement increased (say, to more than 2–300 inhabitants) it became increasingly difficult for a single person to keep track of all hunting, and at the same time the interest in doing so faded for a number of reasons. It is obvious that the number of reports (Lists-of-Game) received in 1983 (2,226; Table 1) did not reflect the number of people actually engaged in hunting. This led to the procedure of trying to estimate non-reported catches. Only in few cases is was possible to check whether these estimates resulted in under-estimating or over-estimating the catch.

The new system, the reporting linked to renewal of hunting licences, is a "direct" approach: Each hunter shall report his own results, and this should be possible independently of the size of the settlement. A main problem may be that many hunters are not used to paper work, and do not see the advantage of making exact notes on the dates and number of hunting objects he is landing. Whether this could lead to under-reporting, over-reporting, or just arbitrary reporting in order to have something on record when renewing the license, is not clear.

The first results of the new system, as presented in the tables of this paper, give rise for some consideration of ways of checking the efficiency and reliability of the new data sets. As mentioned above, the catches reported for ringed seal and hooded seals are within the range estimated on the basis of the previous reporting system. Most of the differences found in respect to seasonal and regional distribution of catches may well be explained by actual variation in catch results from one year to another, or as results of difference in the method of reporting and estimating catches.

The level of harp seal catches reported by the new system is, however, significantly different from that estimated previously. The largest differences were found in some of the districts in Central West and Southwest Greenland, where reporting in the old system was known to be incomplete (see Table 1), and it is quite possible that previous estimates of non-reported

catches of harp seals in these districts were too "conservative", so that total catches were under-estimated during this period. Further, catch and purchase statistics did indicate an increasing trend in harp seal catches since the mid 1970s (Kapel 1986), and this trend may have continued to date. It is thus possible, that the present catch of harp seal in Greenland in fact is in the order of 45,000–55,000 annually, rather than the 20,000–25,000 previously suggested (Kapel 1993).

There is, however, a need for a more close and detailed review of the results obtained from the new system of collecting information on hunting results in Greenland, in order to evaluate its efficiency and draw conclusions on the actual level of catches.

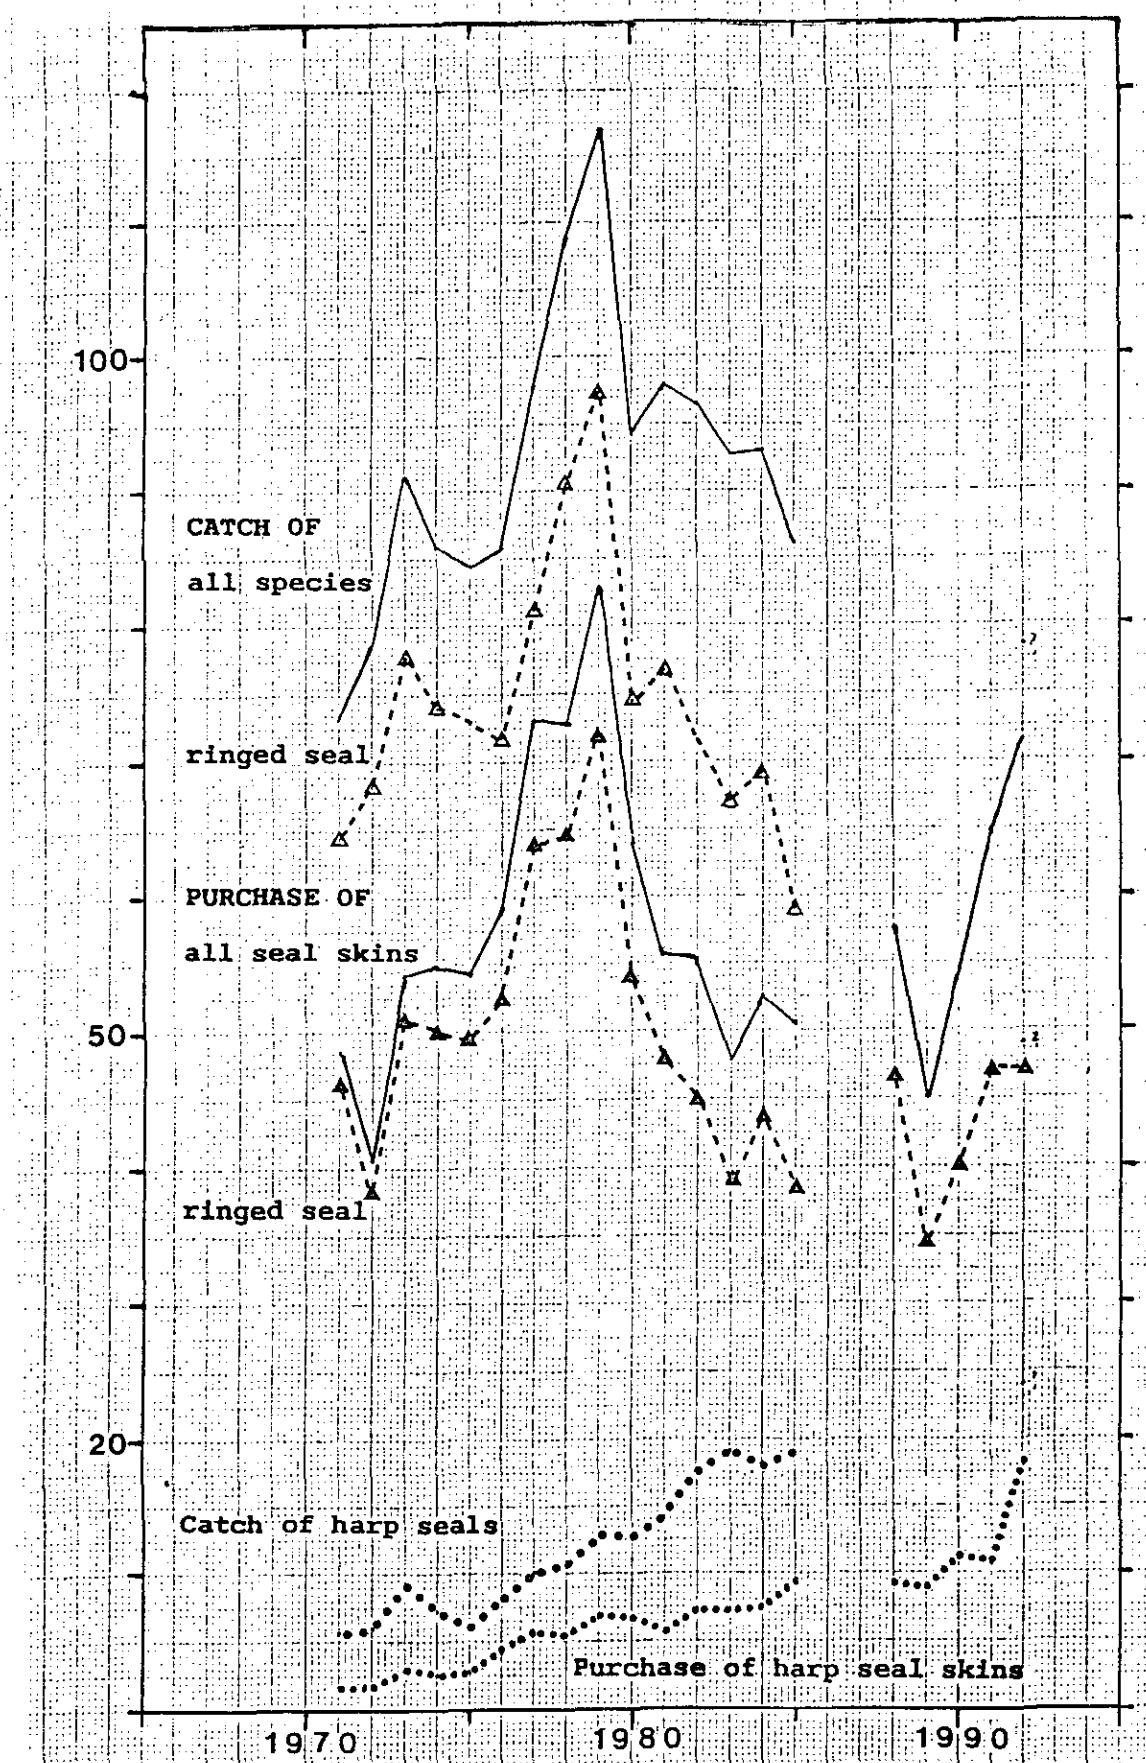

Figure 1. Trends in catch and purchase of seal skins in Greenland, 1971-1992

Annex.

Forms used for collecting hunting statistics in Greenland:

A. Lists-of-Game, form used by list-keepers for reporting the catch of individual hunters, until 1985.

B. Hunting licences, form used by individual hunters when applying for licence renewal, since 1993.

Species account:

English	Latin	Lists-of Game	Hunting licences
Caribou	Rangifer tarandus	1. renér	Tuttu
Polar bear	Ursus maritimus	2. isbjørne	Nanoq
Musk ox	Ovibos moschatus	-	Umimmak
Polar hare	Lepus arcticus	-	Ukaleq
Arctic fox	Alopex lagopus	(trade figures)	Terianniaq
Minke whale	Balaenoptera acutorostrata	3. vågehvaler	-
Narwhal	Monodon monoceros	4. narhvaler	Qilalugaq qernartaq
White whale	Delphinapterus leucas	5. hvidhvaler	Qilalugaq qaqortaq
Pilot whale	Globicephala melaena	6. grinde	
Harbour porpoise	Phocoena phocoena	7. marsvin	Niisa
Other cetaceans	...	8. andre hvaler (specif.)	-
Walrus	Odobenus rosmarus	9. hvalrosser	Aaveg
Ringed seal	Phoca hispida	10. netsider	Natseq
Harbour seal	Phoca vitulina	11. spraglede sæler	Qasigiaq
Bearded seal	Erignathus barbatus	12. remmesæler	Ussuk
Beater (harp <1yr)	Phoca groenlandica	13. blåsider højst 1 år	(incl. in :)
Bedlamer (spotted)	- - -	14. blåsider over 1 år	Allattaq
Saddleback (old)	- - -	15. sortsider	Aataaq
Hooded seal	Cystophora cristata	16. klapmydser	Natsersuaq
Guillemot	Uria lomvia	-	Appa
Eider	Somateria mollissima	-	Miteq
King eider	Somateria spectabilis	-	Qingalik
Ptarmigan	Lagopus mutus	-	Aqisseq
Goose	Anser (albifrons)	-	Nerleg
Kittiwake	Rissa tridactyla	-	Taateraq
Little auk	Alle alle	-	Appaliarsuk
