SCIENTIFIC COUNCIL MEETING - JUNE 1995

Distribution and Abundance of Five Major Groundfish Species at the Continental Slope of
Divisions 3KLMN Based upon Canadian Deepwater Surveys in 1991, 1994 and 1995

by

Introduction

Since about 1989, a deepwater fishery for Greenland halibut has developed at the continental slope of the NAFO Regulatory Area in Div. 3LM and more recently in Div. 3N in depths generally exceeding 1000 meters. In order to evaluate the distribution and abundance of Greenland halibut, in particular, deepwater trawl surveys were conducted in 1991, in Div. 3KLM and in Div. 3KLM and part of Div. 3N in 1994 and 1995. This paper describes the distribution and abundance of five other groundfish species caught during these surveys in addition to Greenland halibut. The five species are American plaice, witch flounder, redfish, roundnose grenadier and roughhead grenadier.

Materials and Methods

All three surveys were conducted by large offshore trawlers with the necessary capacity to fish depths beyond 1500 meters. All surveys were conducted using the same fishing gear i.e. an Engel 145' otter trawl with 18" rockhopper footgear and a 28 mm liner in the codend in order to retain the catch of small fish. To standardize sets within and among surveys, the fishing gear was equipped with electronic sensors which recorded when the net was on the bottom, the wing spread, headline height, towing speed and distance towed. This was done to dispel any concern related to the use of different vessels.

The first survey was carried out by the vessel Cape Adair during Sept. 4-30, 1991 in Div. 3KLM with most sets conducted within a depth range of 750-1500 meters. A total of 106 successful fishing sets were completed, 27 in Div. 3K, 42 in Div. 3L and 37 in Div. 3M. This survey used a line transect design which was later post-stratified according to the stratification scheme described in Bishop (1994).

The second survey was conducted by the vessel Zandvoort during Feb. 3-Mar. 13, 1994 in Div. 3KLMN using a stratified-random design with the stratification scheme discussed above, at depths ranging from 550-1500 meters depending upon the division. A total of 131 successful fishing sets were completed, 22 in Div. 3K, 47 in Div. 3L, 51 in Div. 3M and 11 in Div. 3N.

The 1995 survey was carried out during Mar. 16-April 21 by the Canadian research vessel Teleost in Div. 3KLMN using the same stratified-random design as in 1994 in depths of 500-1500 meters with more extensive coverage in Div. 3K than the previous two surveys. A total of 142 successful sets were conducted, 48 in Div. 3K, 48 in Div. 3L, 37 in Div. 3M and 9 in Div. 3N.

At the end of each fishing set the catch numbers and weights (kg) were collected for each species caught and where time was available, length frequencies were obtained for the major groundfish species encountered.

Results

American plaice

The distribution of American plaice as mean weight (kg) and mean number per set for each survey year are presented in figures 1 and 2, respectively. In the 1991 survey there were virtually no American plaice with the exception of several small catches on the northwest side of the Flemish Cap in relatively deep water (Fig. 1 and 2). In the 1994 survey, the catches were more frequent than in 1991 except for northern Div. 3K and in the deeper waters of the Flemish Pass. The area of highest density was along the northwest slope of Div. 3L inside the Canadian fishery zone and the southwest slope of the Flemish Pass in Div. 3L. Consistent catches were also taken on the northeast slope of Div. 3N although this area was not surveyed in 1991 for comparison. The distribution in 1995 was very similar to that of 1994. In 1995, however, survey coverage was extended to the 500-750 meter depth zone in Div. 3K. American plaice were caught consistently throughout this depth zone but were generally low compared to areas of highest density to the south.

Biomass and abundance indices separately by stratum and division are presented in tables 1 and 2, respectively. For the area surveyed in Div. 3K there were essentially no American plaice encountered in the 1991 and 1994 surveys. In 1995, on the other hand, the biomass was estimated to be about 1700 tons (Table 1) and the abundance, 8 million fish (Table 2). Most of the estimate is accounted for in the depth zone 500-750 meters. For commonly fished strata between 1994 and 1995 still show virtually no fish. In Div. 3L there were no fish estimated for 1991 but in 1994 was estimated to be about 7400 tons and 27 million fish. This increased to 13000 tons and 52 million fish in the 1995 survey. For commonly fished strata in Div. 3L between 1994 and 1995 the estimates were much lower than the estimates for all strata fished, however, the ratio between the two years was about the same for both. The biomass and abundance estimates for Div. 3M increased from just 30 tons and 50 thousand fish in 1991 to 1400 tons and 1.7 million fish in 1994 and remaining much the same for 1995. For Div. 3N the estimates were about the same between 1994 and 1995 at around 1700 tons and 5 million fish.

The overall estimate of biomass and abundance in 1995 for the surveyed area of Div. 3KLMN was 18000 tons and 66 million fish respectively.

Age-length comparisons of American plaice

The presence of increasing numbers of American plaice in the very deep waters on both sides of the Flemish Pass was considered unusual in comparison to the typical distribution of American plaice in previous years. It is known that there is a considerable difference in the growth rates of this species between those of the Grand Bank and those of the Flemish Cap (Bowring and Brodie 1994). Age samples were therefore collected in 1994 from the west side (Div. 3L) of the Pass and the east side (Div. 3M) to determine the origin of the fish in the deepwater or the extent of any mixing. A plot of the mean length at age for the two samples by sex is presented in figure 3. A comparison of the Div. 3L sample with similar data from the regular groundfish survey on the northern Grand Bank is shown in figure 4.

The results presented in figure 3 indicate that the samples examined are from the respective stocks adjacent to where they were collected and do not appear to be confounded by mixing within the Flemish Pass area. This is further confirmed by the comparison in figure 4 where the mean sizes at age are virtually identical.

Witch flounder

The distribution of witch flounder as mean weight (kg) and mean number per set for each survey year are presented in figures 5 and 6, respectively. As with the American plaice, there were very few witch flounder caught in the 1991 survey except for a few sets with very low catches. In 1994, witch flounder were caught in more than half of the sets but at consistently low catches and widely dispersed throughout the survey area. In 1995, they were caught in most sets. Catch levels were generally in the range of the 1994 catches, although there were some localized areas of higher density in the southern Flemish Pass area.

Except for Div. 3N which showed some decline between 1994 and 1995, the biomass (Table 3) and abundance (Table 4) increased in all divisions from 1991 to 1995, although the overall estimates remained low. In 1995 the cumulative total was around 5000 tons of biomass and 12 million fish for Div. 3KLMN combined compared to 2400 tons and 4 million fish in 1994.

Redfish

The distribution of redfish as mean weight (kg) and mean number per set for each survey year are presented in figures 7 and 8, respectively. During the 1991 survey redfish were encountered in few areas being most prevalent on the nose of the Grand Bank in the area known as the Sackville Spur. Some catches were taken around the upper part of the Flemish Cap at relatively shallow depths. The largest catch was taken in the northernmost part of Div. 3K, however, there were few other catches in that division that had any redfish. In the 1994 survey, there were no redfish caught in Div. 3K and the northernmost part of Div. 3L. Although there were no catches taken in the deeper waters of Flemish Pass there were catches taken along the upper slopes on both sides of the Pass. The catches were most highly concentrated on the southwest end of the Flemish Cap in the area known as the Beothuck Knoll with several good catches taken on the northwestern side of the Cap in shallower waters.

Very little redfish was found in any year in either Div. 3K, 3L or Div. 3N (Tables 5 and 6). In Div. 3K in 1991 biomass was estimated to be over 4000 tons (Table 5) and 7 million fish (Table 6), however, this estimate was influenced by one large catch in the northern part of the division. The only area where significant amounts of redfish were encountered was in Div. 3M. In 1991 less than 200 tons of biomass was estimated but the biomass estimate for 1994 increased to nearly 8000 tons then declined to 4400 tons in 1995. In both years almost the entire biomass and abundance is accounted for by one or two strata as evident from the distribution plots.

Roundnose grenadier

Roundnose grenadier were widely distributed throughout the survey area in all three years (Fig. 9 and 10). The area of highest concentration encountered was in Div. 3K at the extreme north of the area surveyed in the deepest strata. This was the same for all three years. However, this area of concentration seemed to be less extensive in the 1995 survey than in each of the previous surveys. In 1994 and 1995 there were some larger catches on the north side of the Flemish Cap and at the southern tip of the Cap south of the Beothuck Knoll. In 1991 there was a significant number of large sets in the northern Flemish Pass area, however, this did not appear to be as much the case for 1994 and 1995.

The biomass and abundance of roundnose grenadier are presented by division and stratum in tables 7 and 8 respectively. The survey biomass index of roundnose grenadier has declined considerably between 1994 and 1995 in all divisions. The bulk of the biomass and abundance are found in Div. 3K and 3M which generally account for more than 50% and 25% of the total area estimates, respectively. The biomass in Div. 3K declined from about 20000 tons in 1991 and 1994 to less than 7000 tons in 1995 (Table 7). In Div. 3M the biomass estimates declined from about 12000 tons in 1991 to 8500 tons in 1994 and 4400 tons in 1995. The trends were the same for the entire survey area as well as the area of common strata fished. The abundance index for Div. 3K increased considerably between 1991 and 1994 compared to a stable index of biomass suggesting a preponderance of smaller fish in the 1994 survey compared to 1991. Otherwise the ratios of biomass and abundance was about the same in all other areas and years.

Roughhead grenadier

As with the roundnose grenadier the roughhead grenadier was also widely distributed throughout the survey areas in all three surveys (Fig. 11 and 12). In 1991 there were no clear areas of high concentration. In both 1994 and 1995, however, there were areas of higher concentration especially in the Flemish Pass and along the northeast slope of Div. 3L and the eastern slope of Div. 3N. No apparent concentrations were observed in Div. 3K but catches seemed to be evenly distributed at similar levels in all three years.

All four of Div. 3KLM appear to have significant amounts of roughhead grenadier (Tables 9 and 10) although Div. 3L and 3M generally account for most of the stock biomass and abundance. The biomass and abundance increased systematically from 1991 to 1995 in all divisions. In 1991 the total estimated biomass for Div. 3KLM was 16000 tons (no survey conducted in Div. 3N in 1991) compared to 25000 tons in 1995 (about 6000 tons in Div. 3N). The abundance increased from about 27 million fish in 1991 in Div. 3KLM to 82 million fish in 1995 (10 million fish in Div. 3N in 1995).

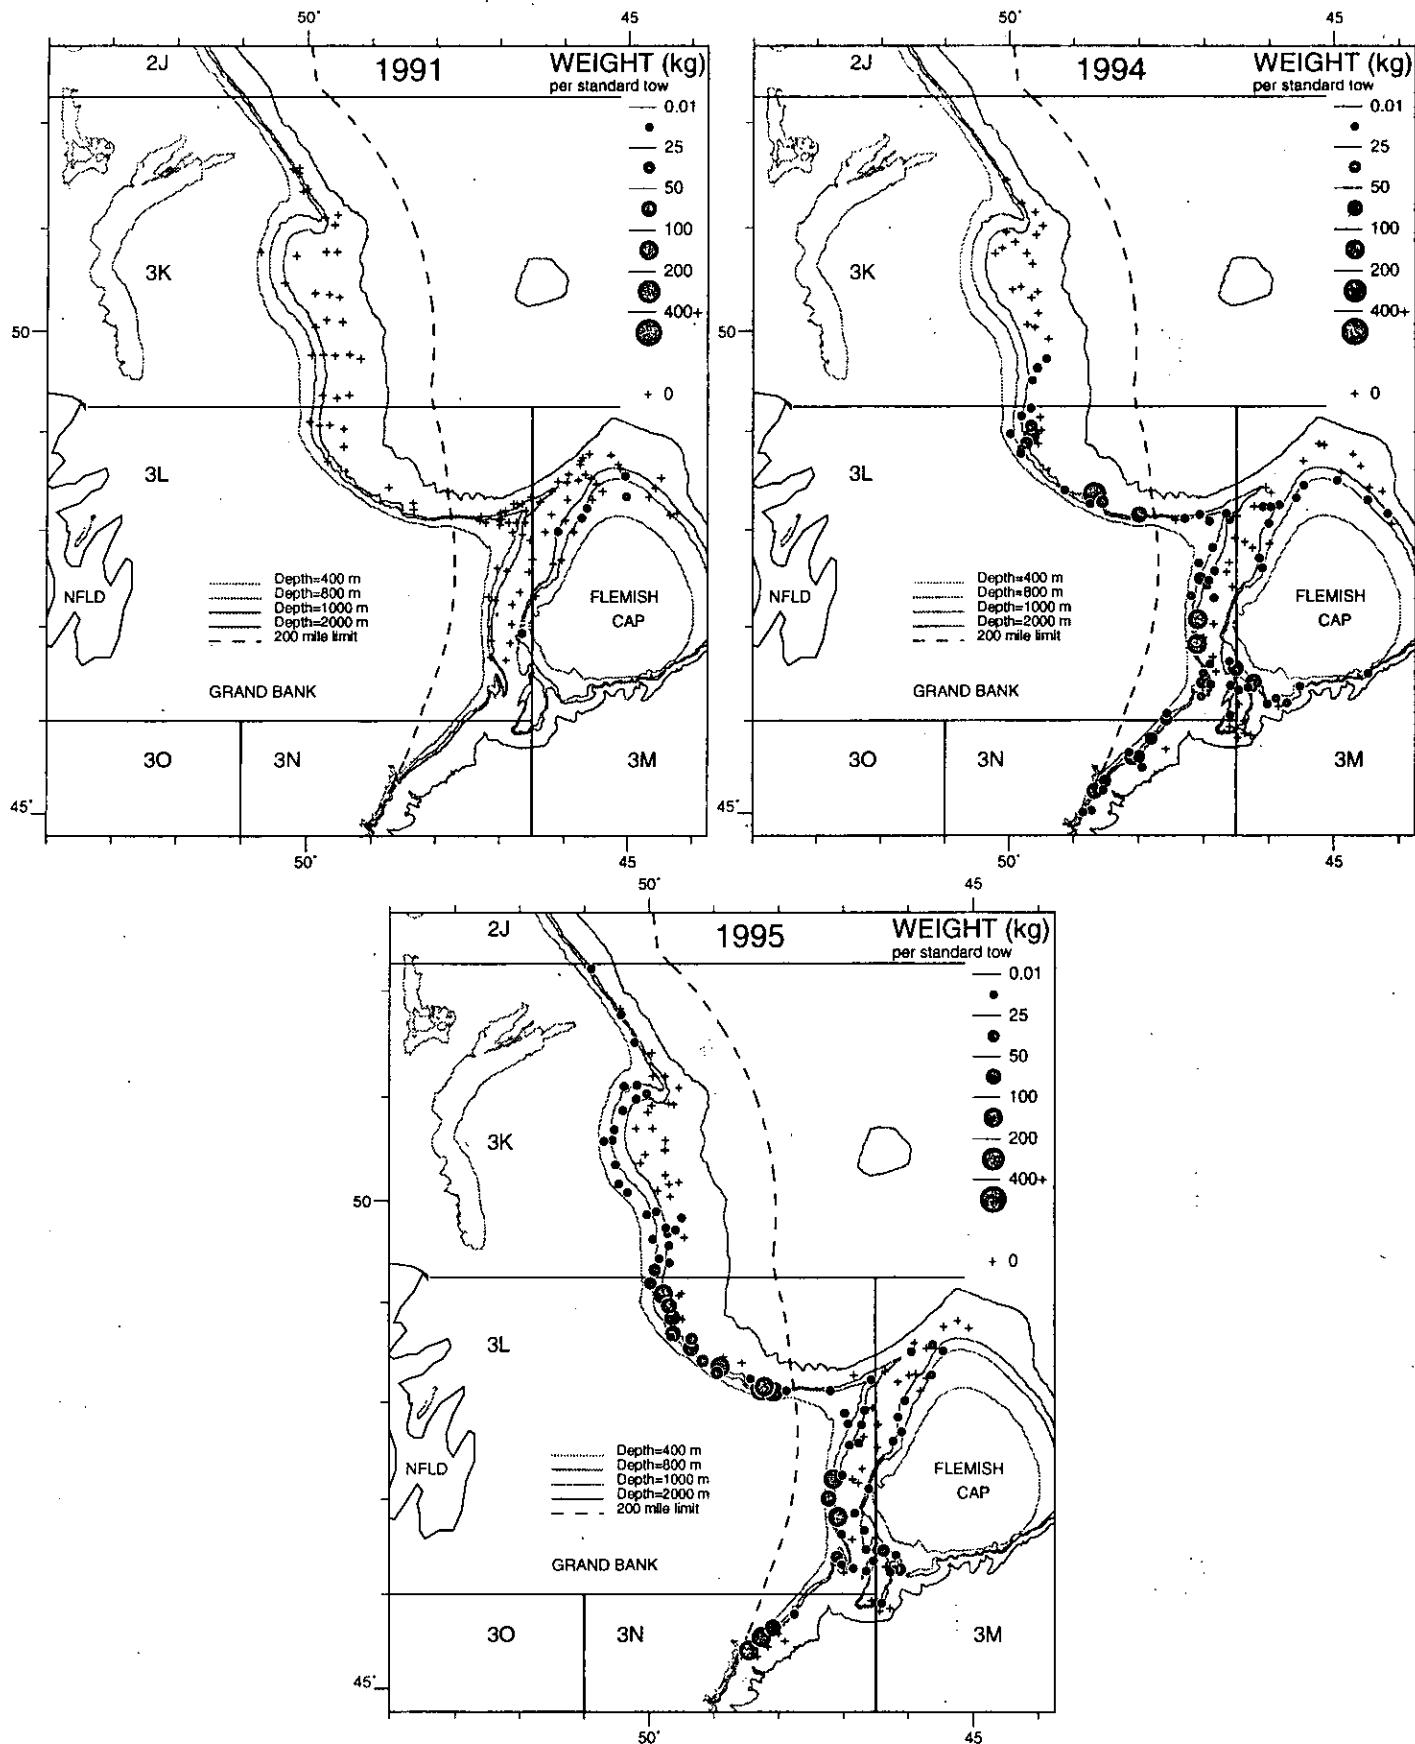

Fig. 1. Distribution of American plaice catches from Greenland halibut directed Canadian surveys of NAFO Divisions 3KLMN from 1991-1995. Surveys were conducted by the Cape Adair (1991, 650 m - 1800 m), Zandvoort (1994, 750 m - 1500 m) and FRV Teleost (1995, 500 m - 1700 m). Circles represent catch weight (kg) per standard tow (1.75 nautical miles). Dashed line represents division between the Canadian economic zone and the NAFO Regulatory area (east of line)

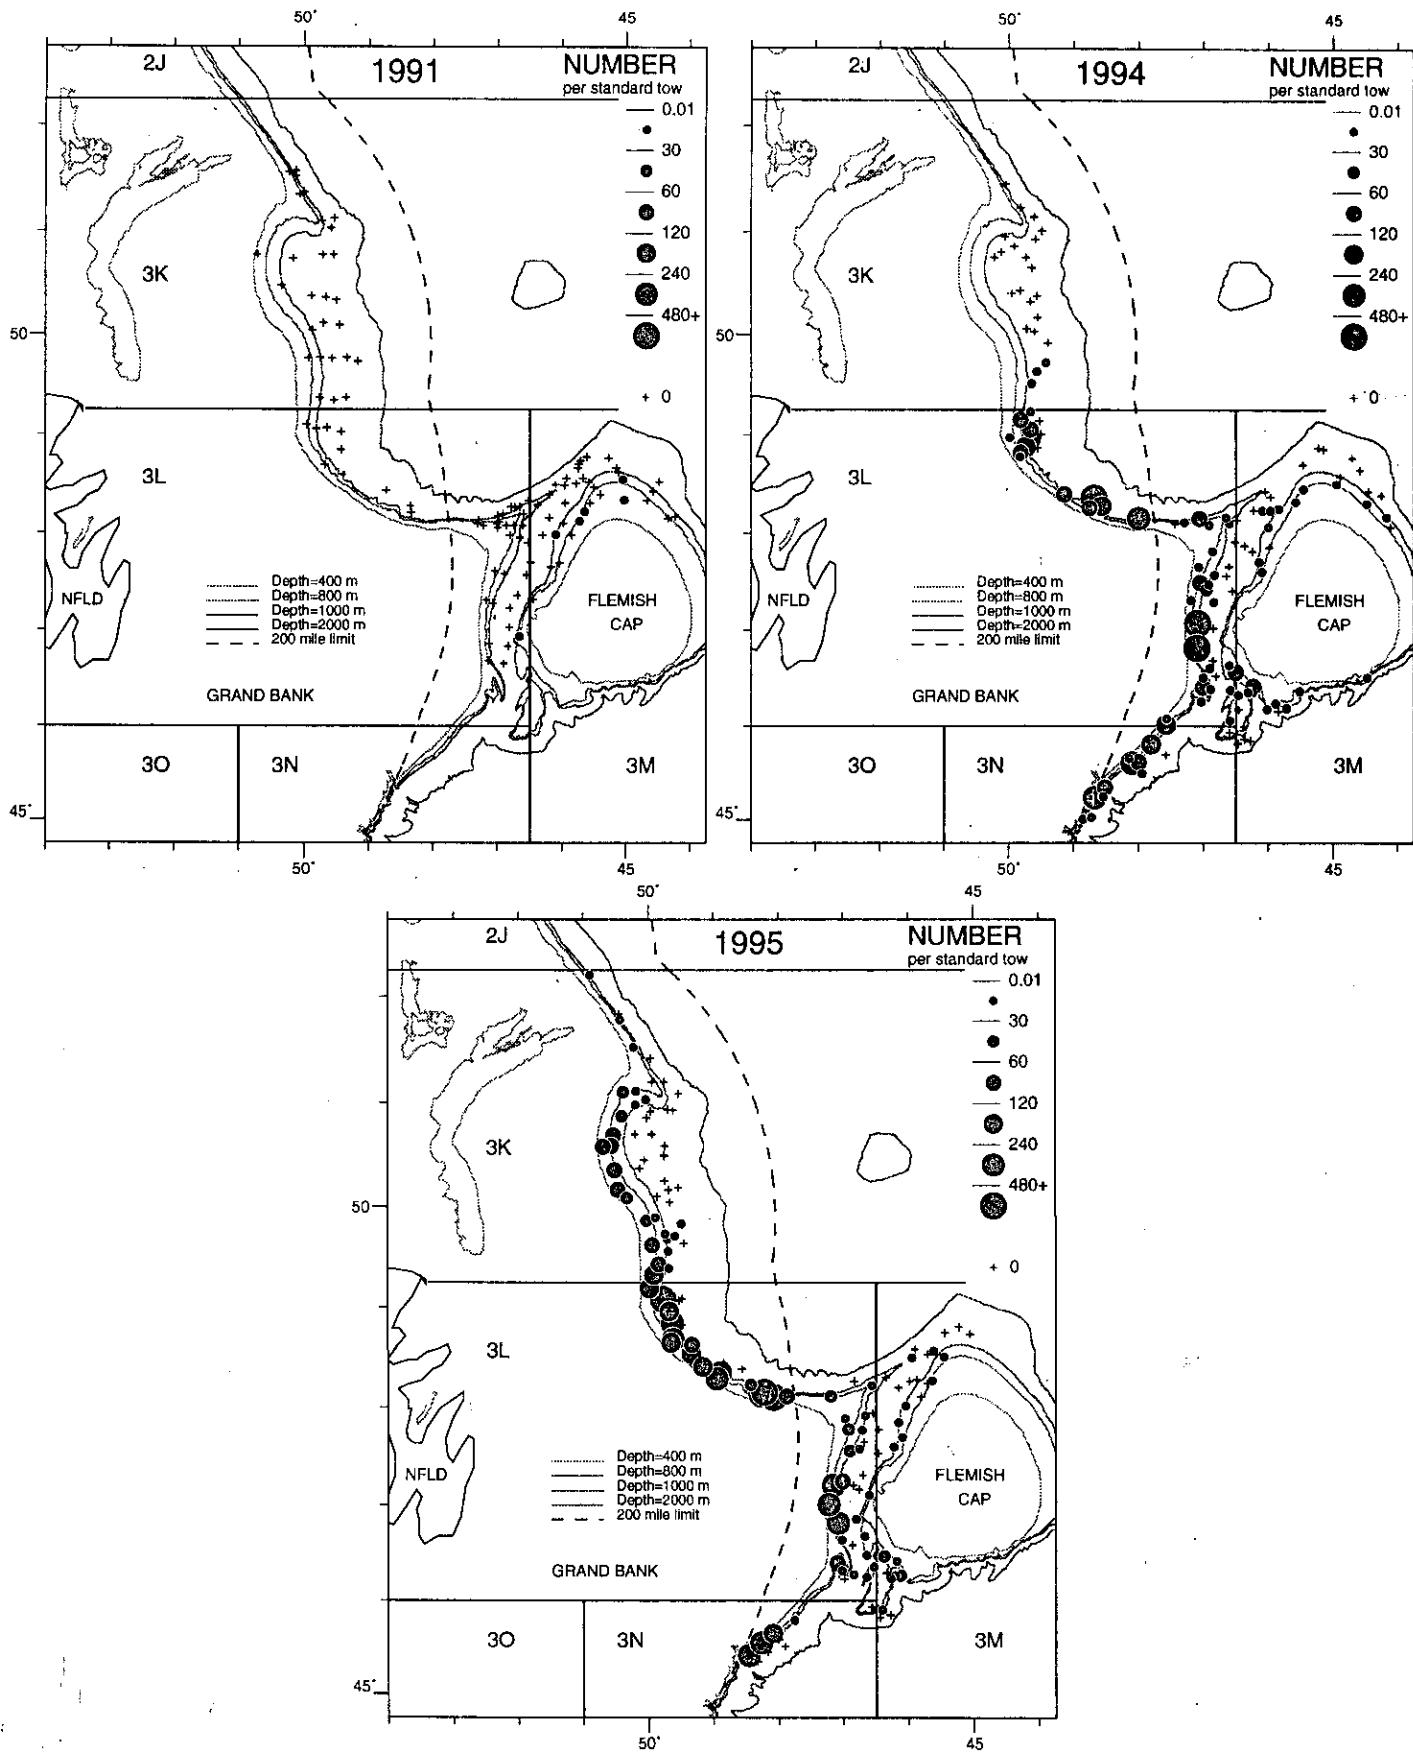

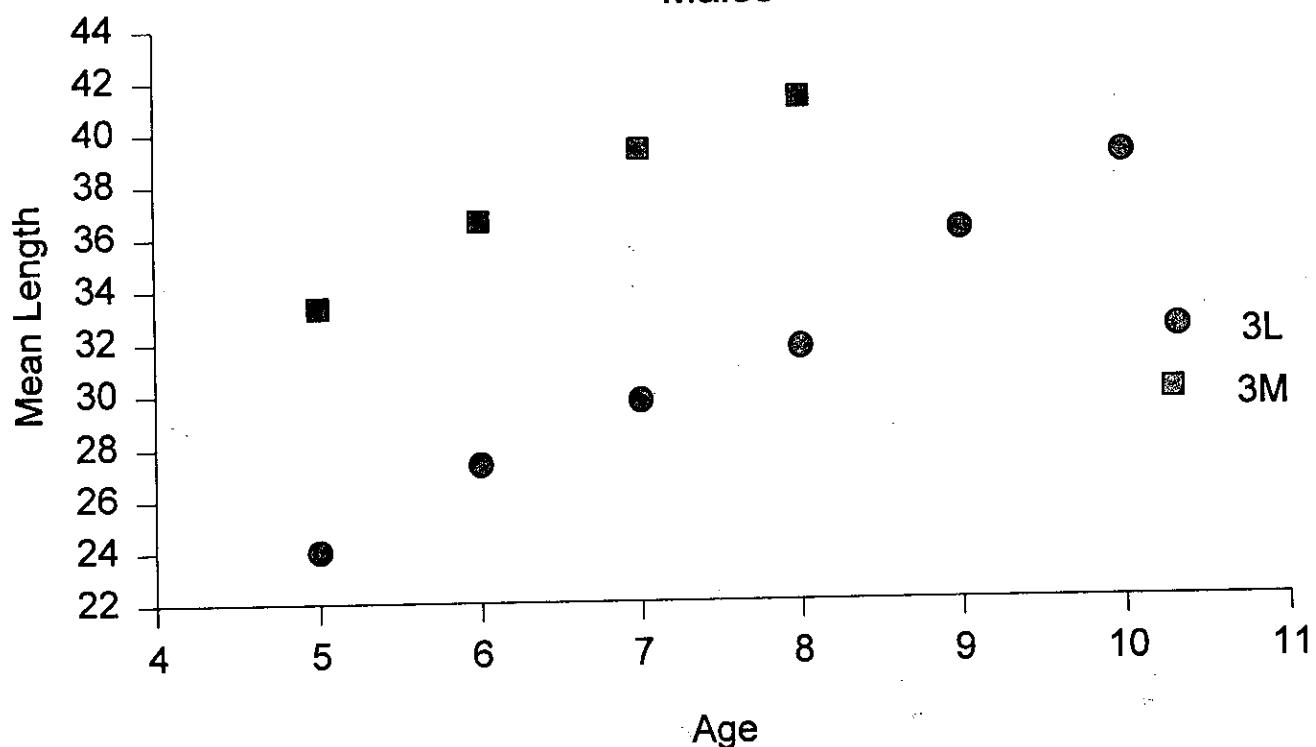

Fig. 2. Distribution of American plaice catches from Greenland halibut directed Canadian surveys of NAFO Divisions 3KLMN from 1991-1995. Surveys were conducted by the Cape Adair (1991, 650 m - 1800 m), Zandvoort (1994, 750 m - 1500 m) and FRV Teleost (1995, 500 m - 1700 m). Circles represent catch number per standard tow (1.75 nautical miles). Dashed line represents division between the Canadian economic zone and the NAFO Regulatory area (east of line)

Males

Females

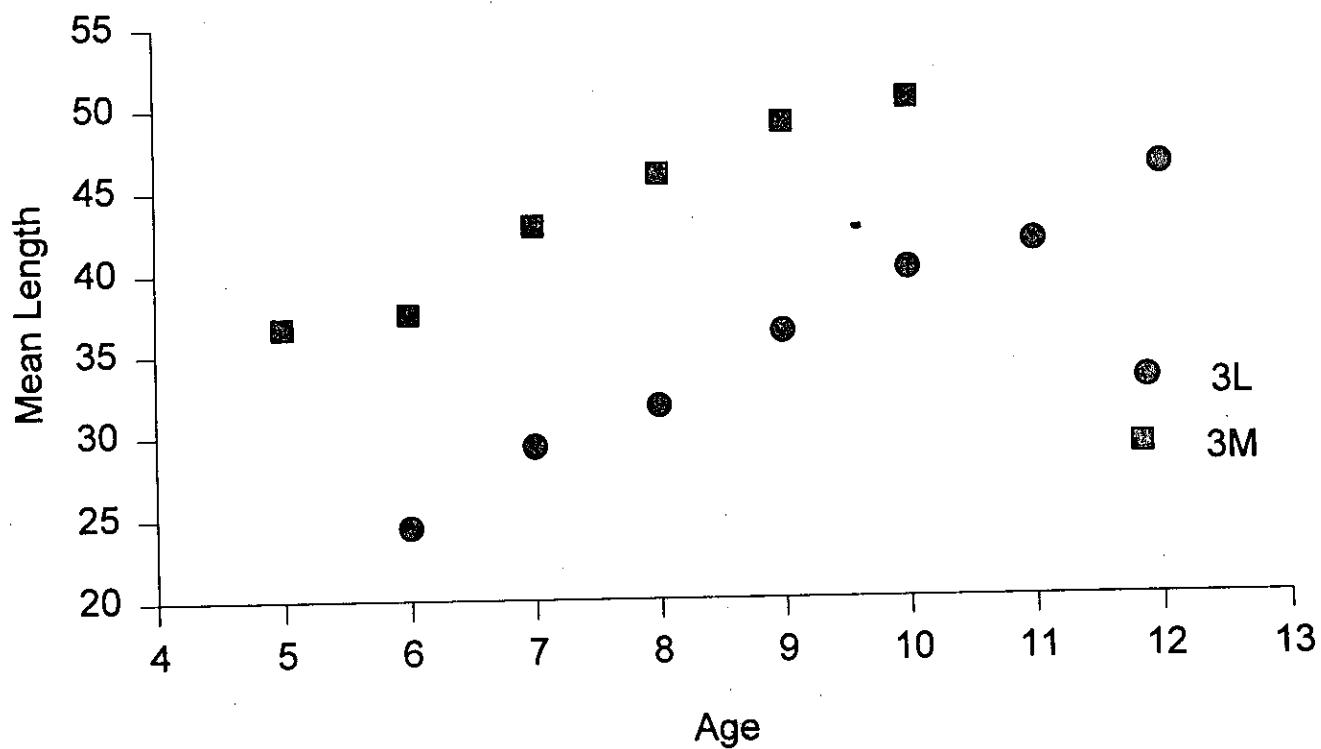

Figure 3. Mean length at age for American plaice collected on the east (3M) west (3L) sides of the Flemish Pass.

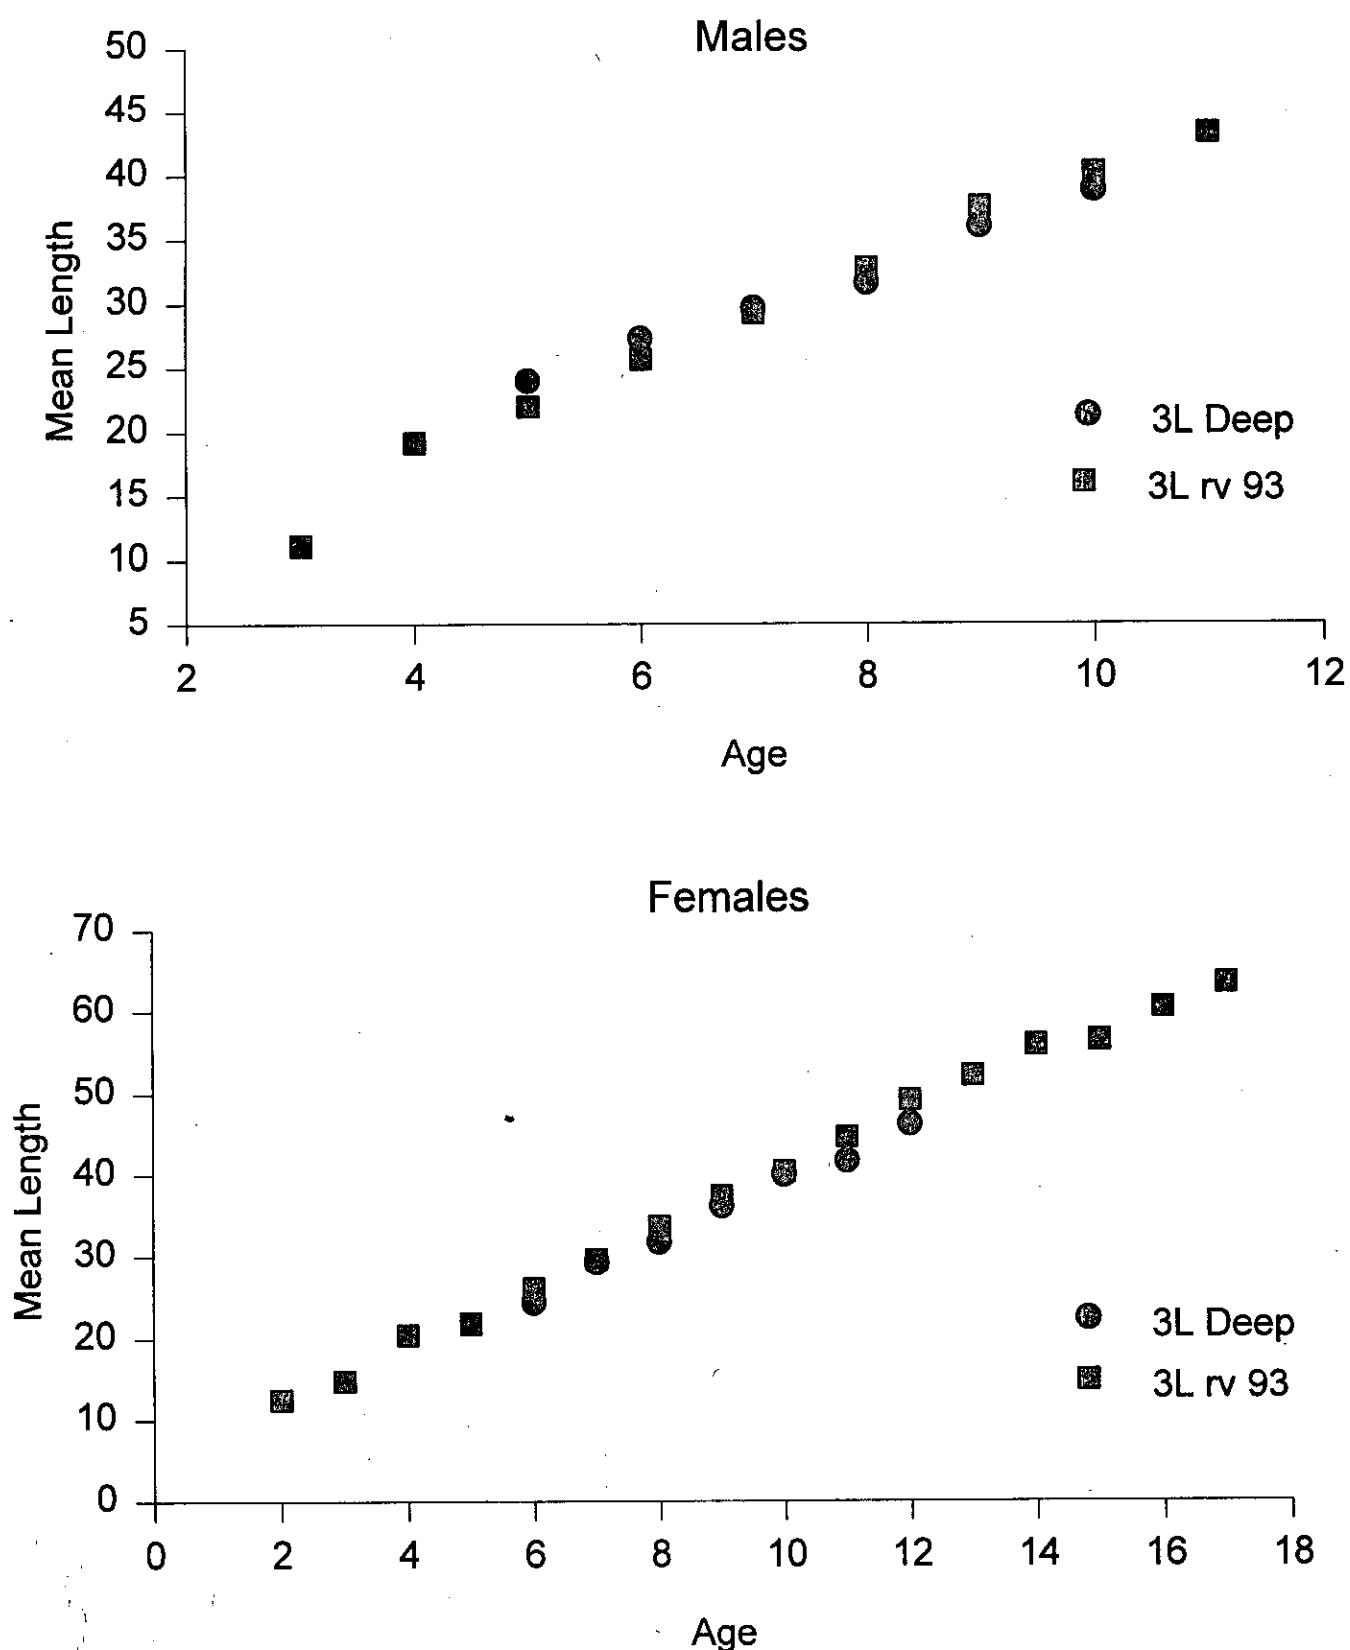

Figure 4. Mean length at age of American plaice collected from the west side of the Flemish Pass (3L deep) and from the Canadian spring research vessel survey in 3L in 1993 (3L rv 93).

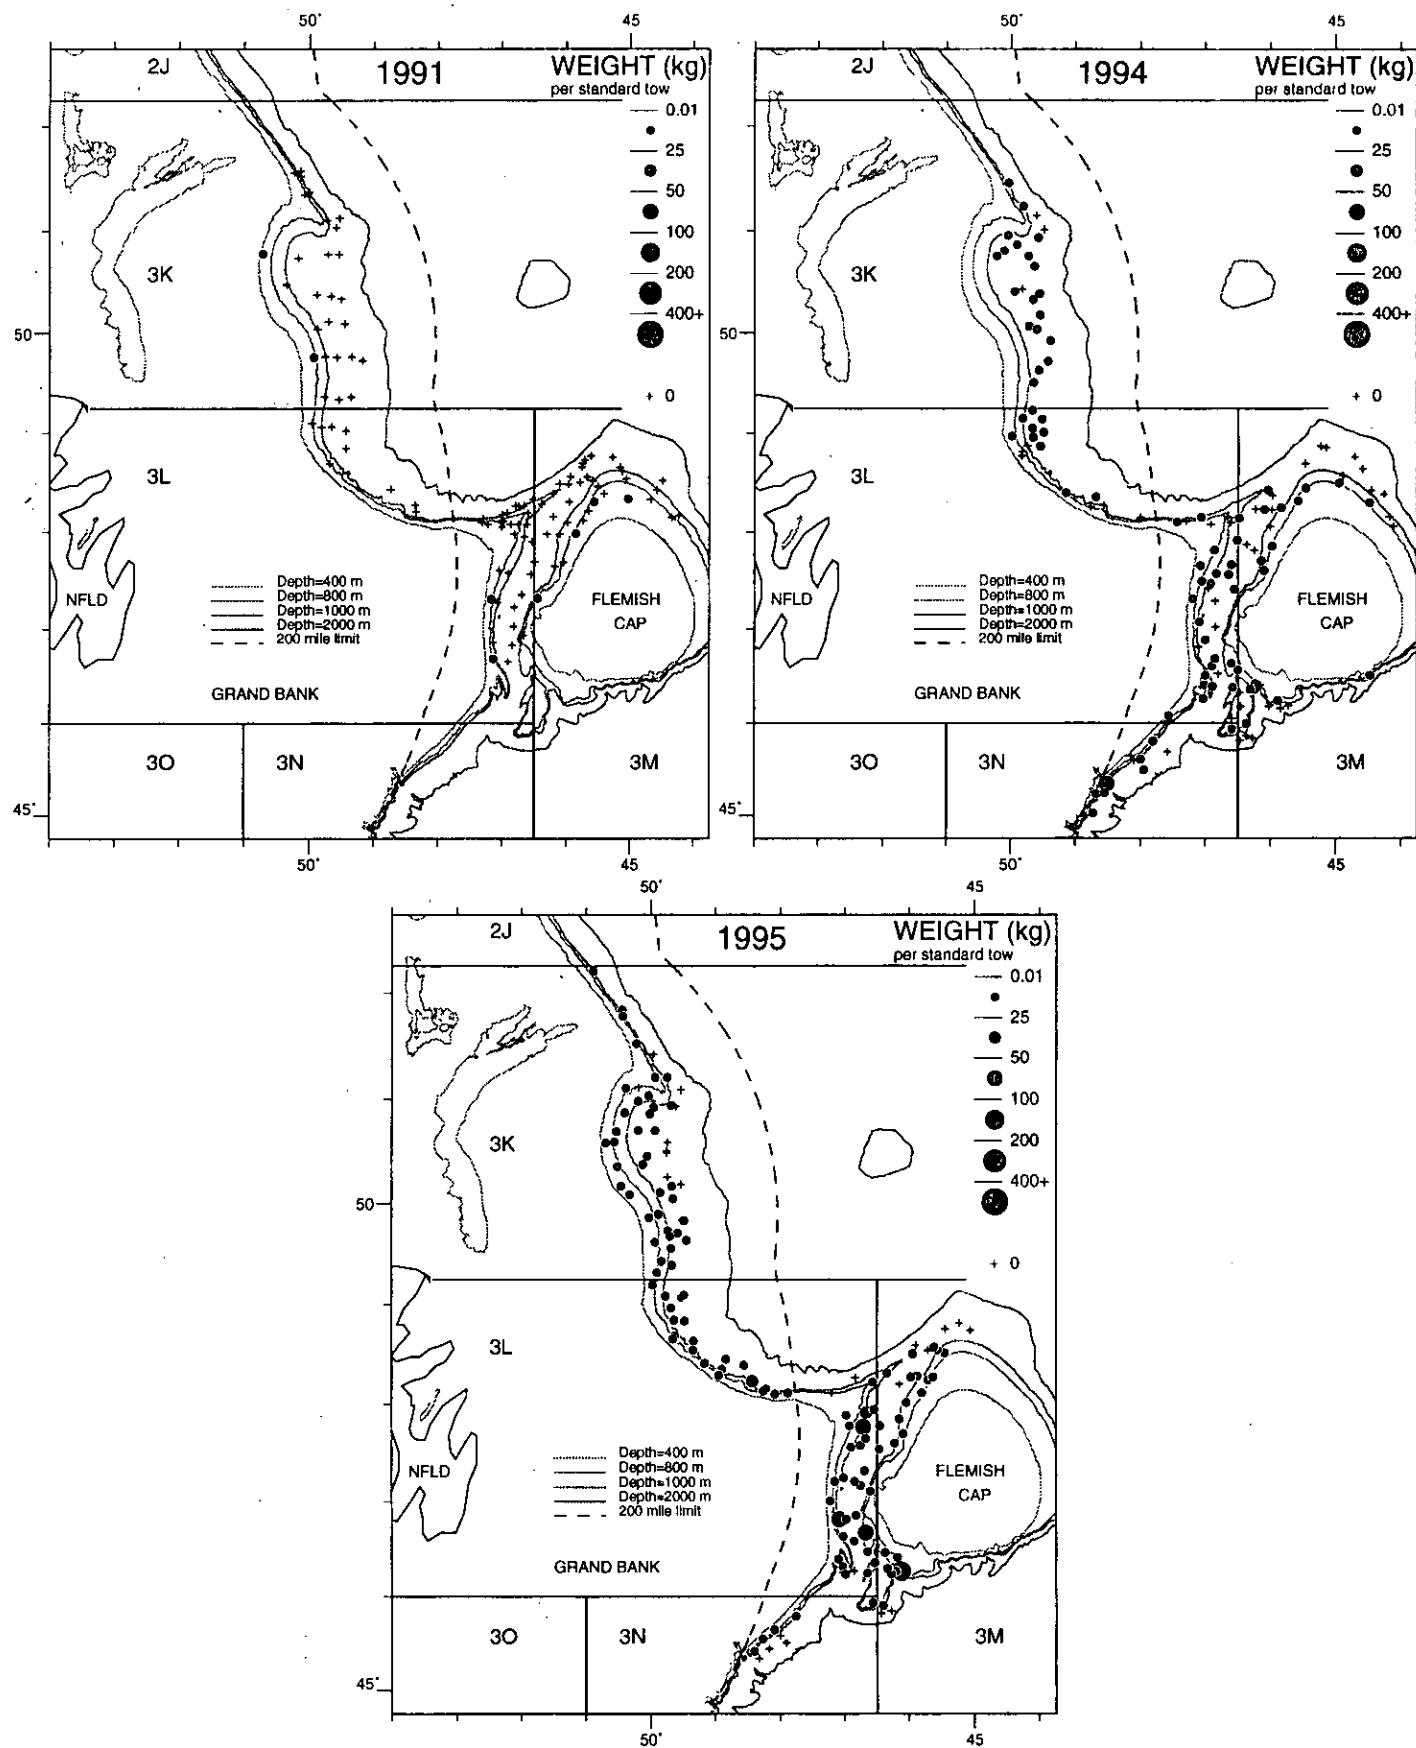

Fig. 5. Distribution of witch flounder catches from Greenland halibut directed Canadian surveys of NAFO Divisions 3KLMN from 1991-1995. Surveys were conducted by the Cape Adair (1991, 650 m - 1800 m), Zandvoort (1994, 750 m - 1500 m) and FRV Teleost (1995, 500 m - 1700 m). Circles represent catch weight (kg) per standard tow (1.75 nautical miles). Dashed line represents division between the Canadian economic zone and the NAFO Regulatory area (east of line)

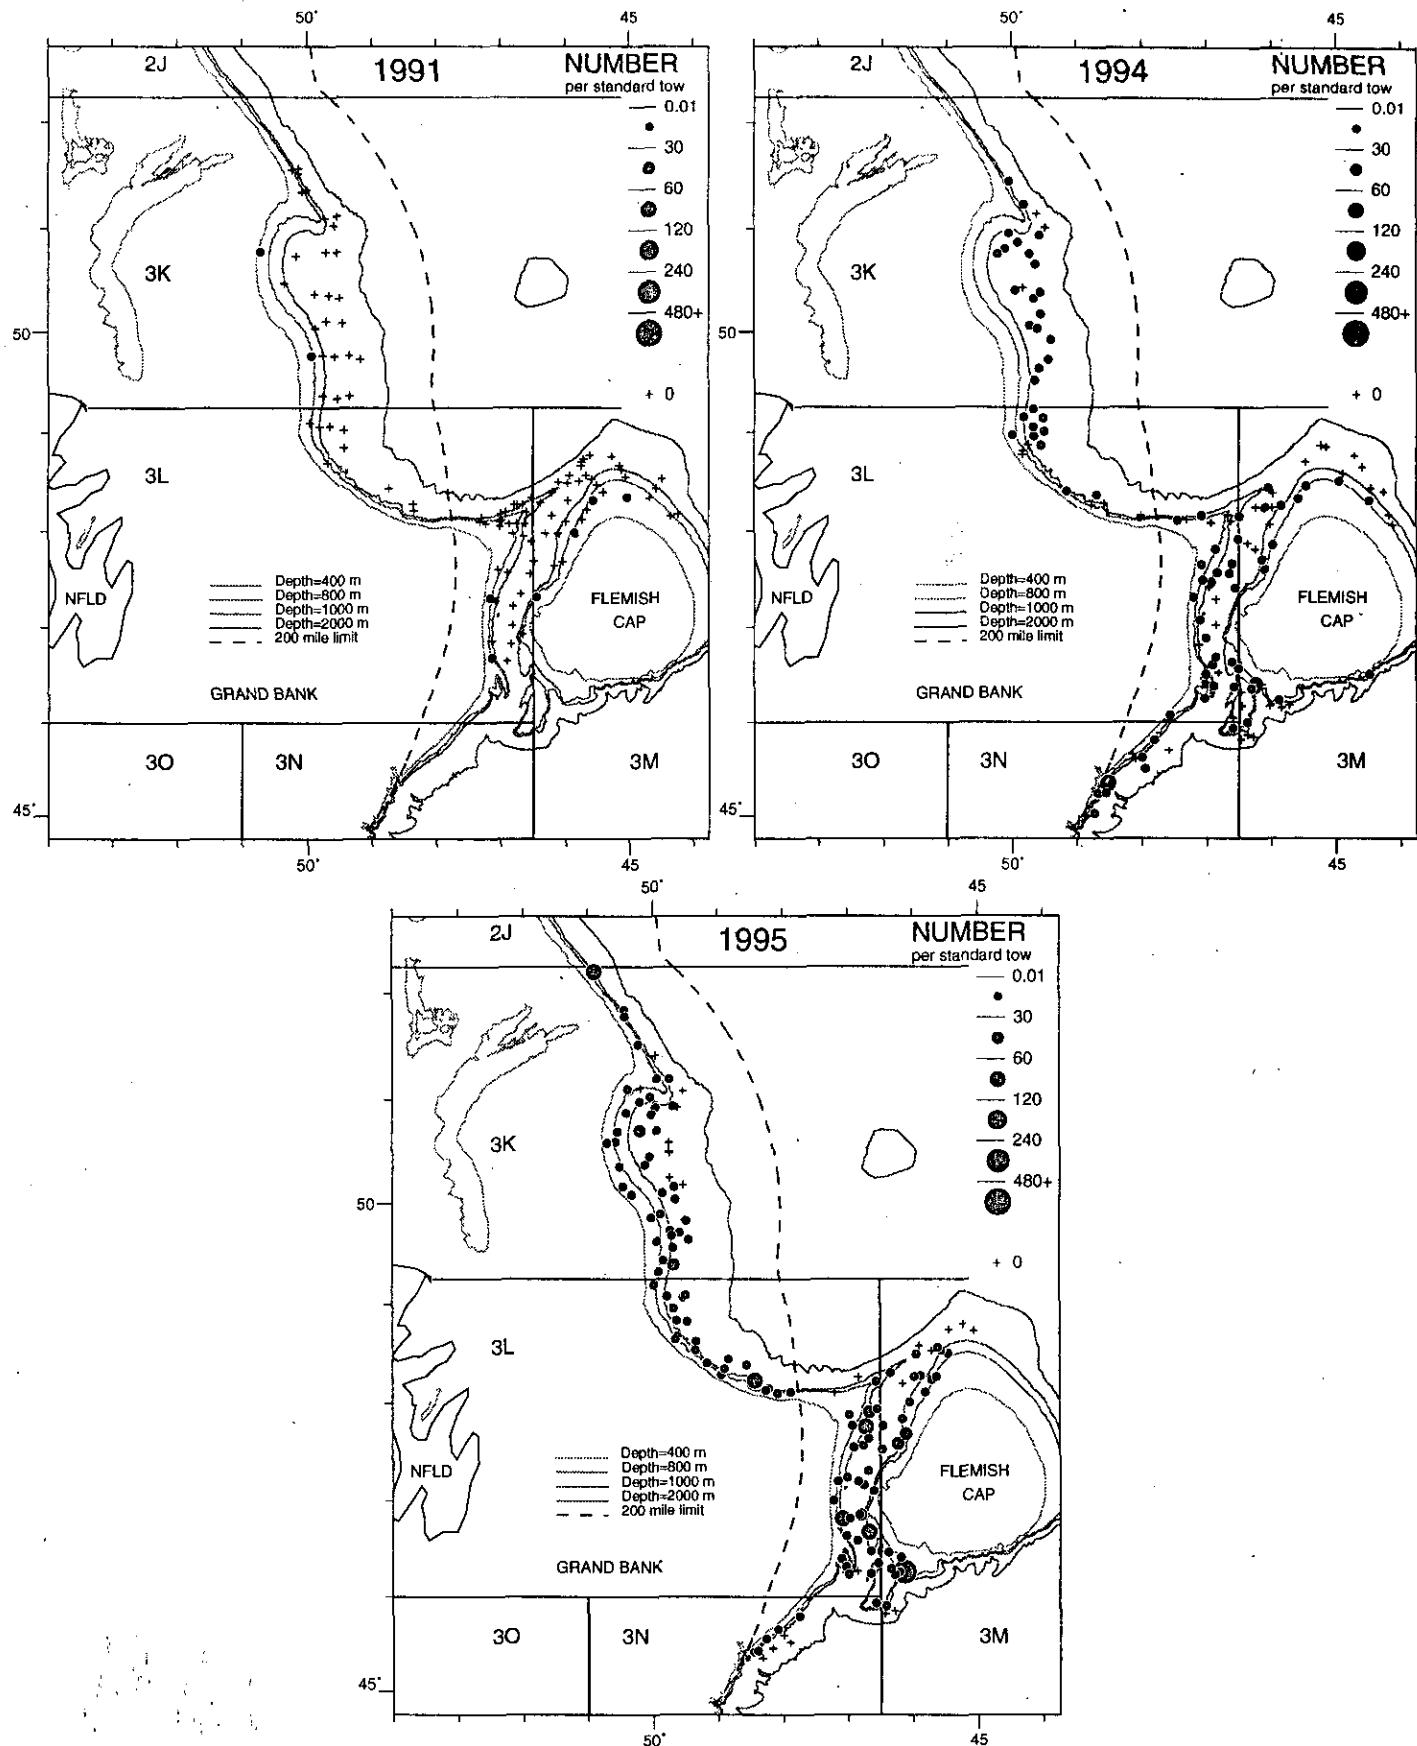

Fig. 6. Distribution of witch flounder catches from Greenland halibut directed Canadian surveys of NAFO Divisions 3KLMN from 1991-1995. Surveys were conducted by the Cape Adair (1991, 650 m - 1800 m), Zandvoort (1994, 750 m - 1500 m) and FRV Teleost (1995, 500 m - 1700 m). Circles represent catch number per standard tow (1.75 nautical miles). Dashed line represents division between the Canadian economic zone and the NAFO Regulatory area (east of line)

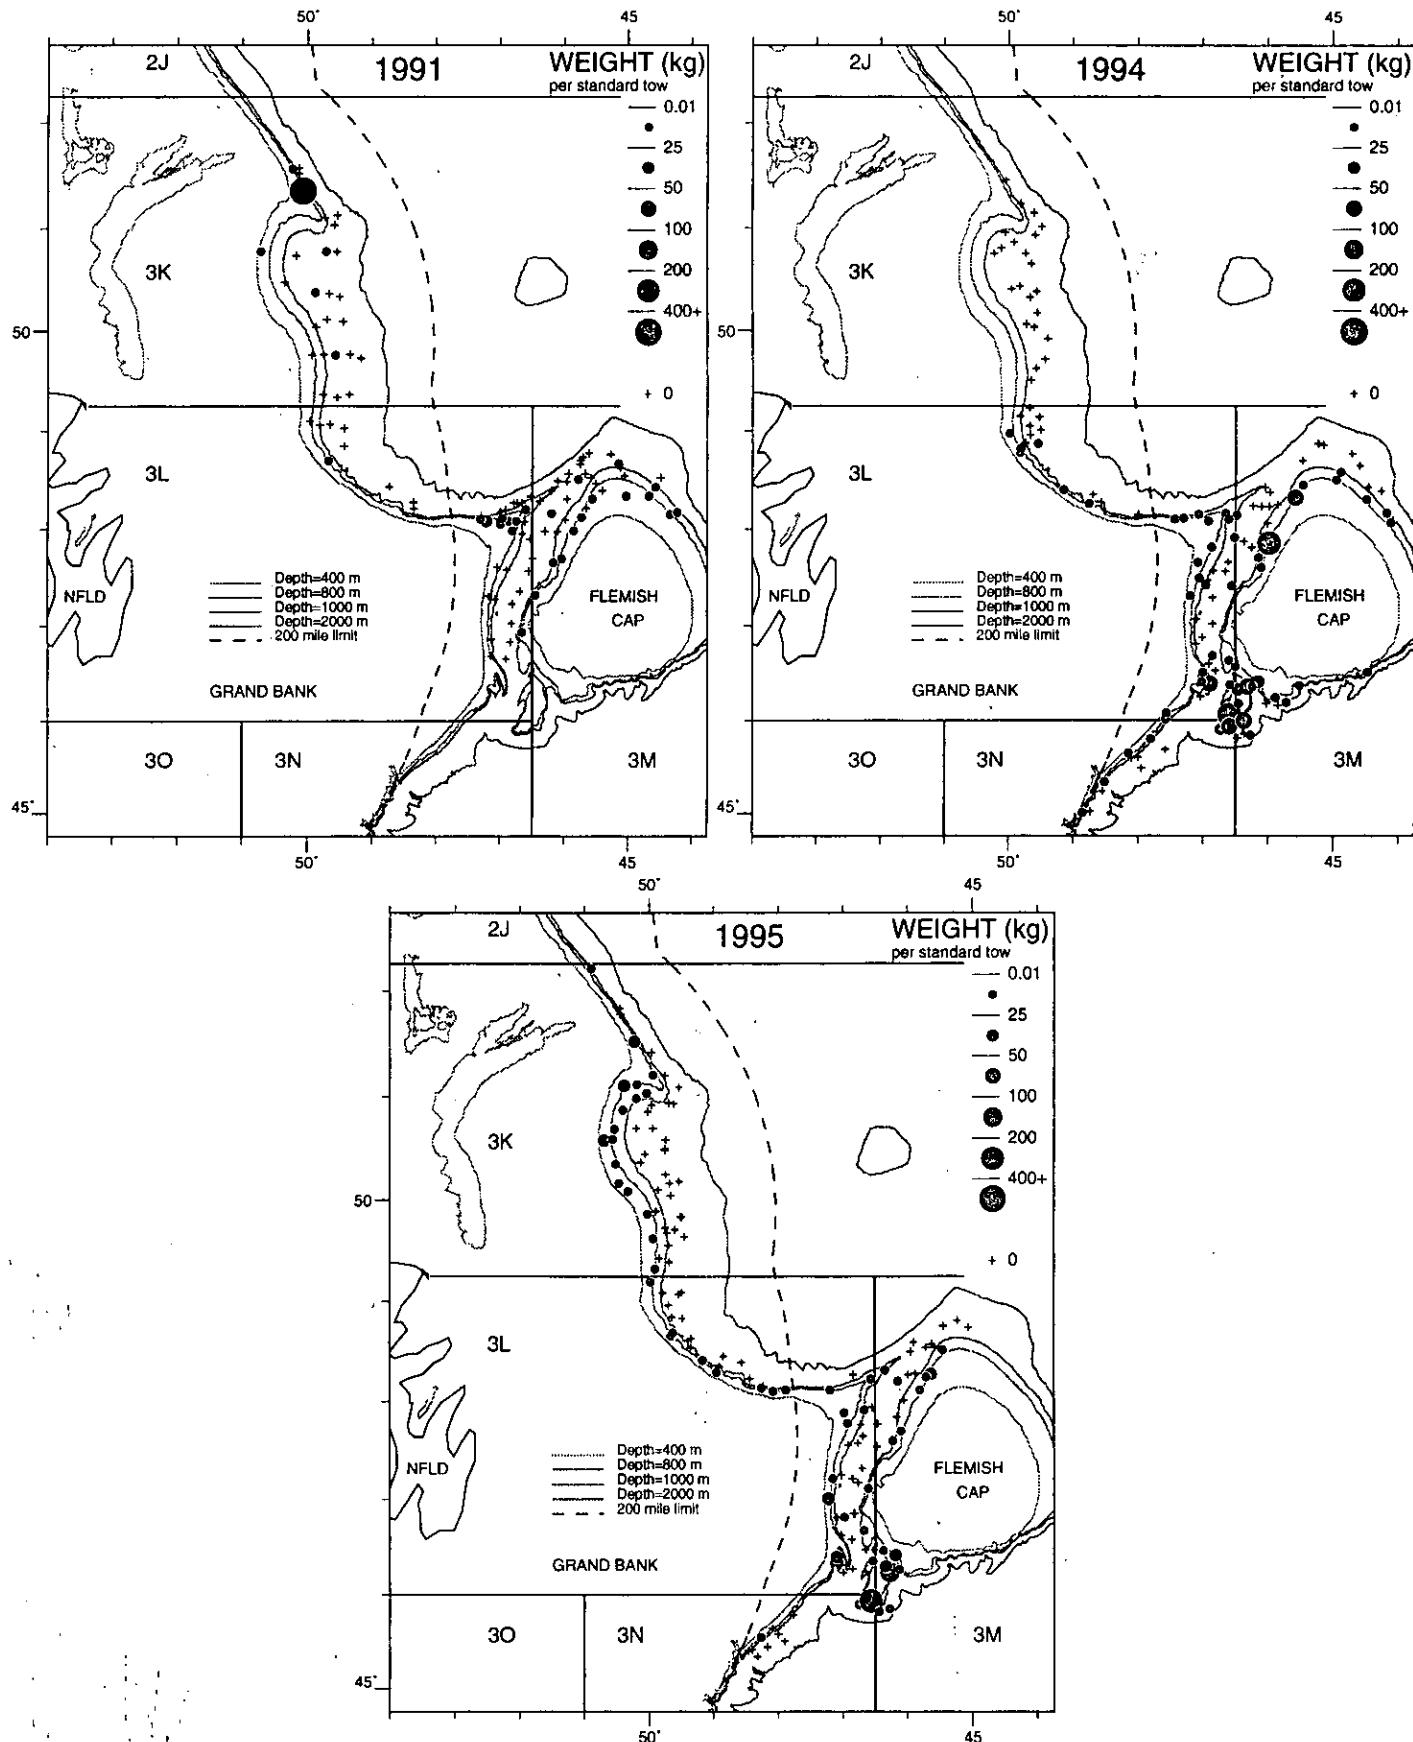

Fig. 7. Distribution of redfish catches from Greenland halibut directed Canadian surveys of NAFO Divisions 3KLMN from 1991-1995. Surveys were conducted by the Cape Adair (1991, 650 m - 1800 m), Zandvoort (1994, 750 m - 1500 m) and FRV Teleost (1995, 500 m - 1700 m). Circles represent catch weight (kg) per standard tow (1.75 nautical miles). Dashed line represents division between the Canadian economic zone and the NAFO Regulatory area (east of line)

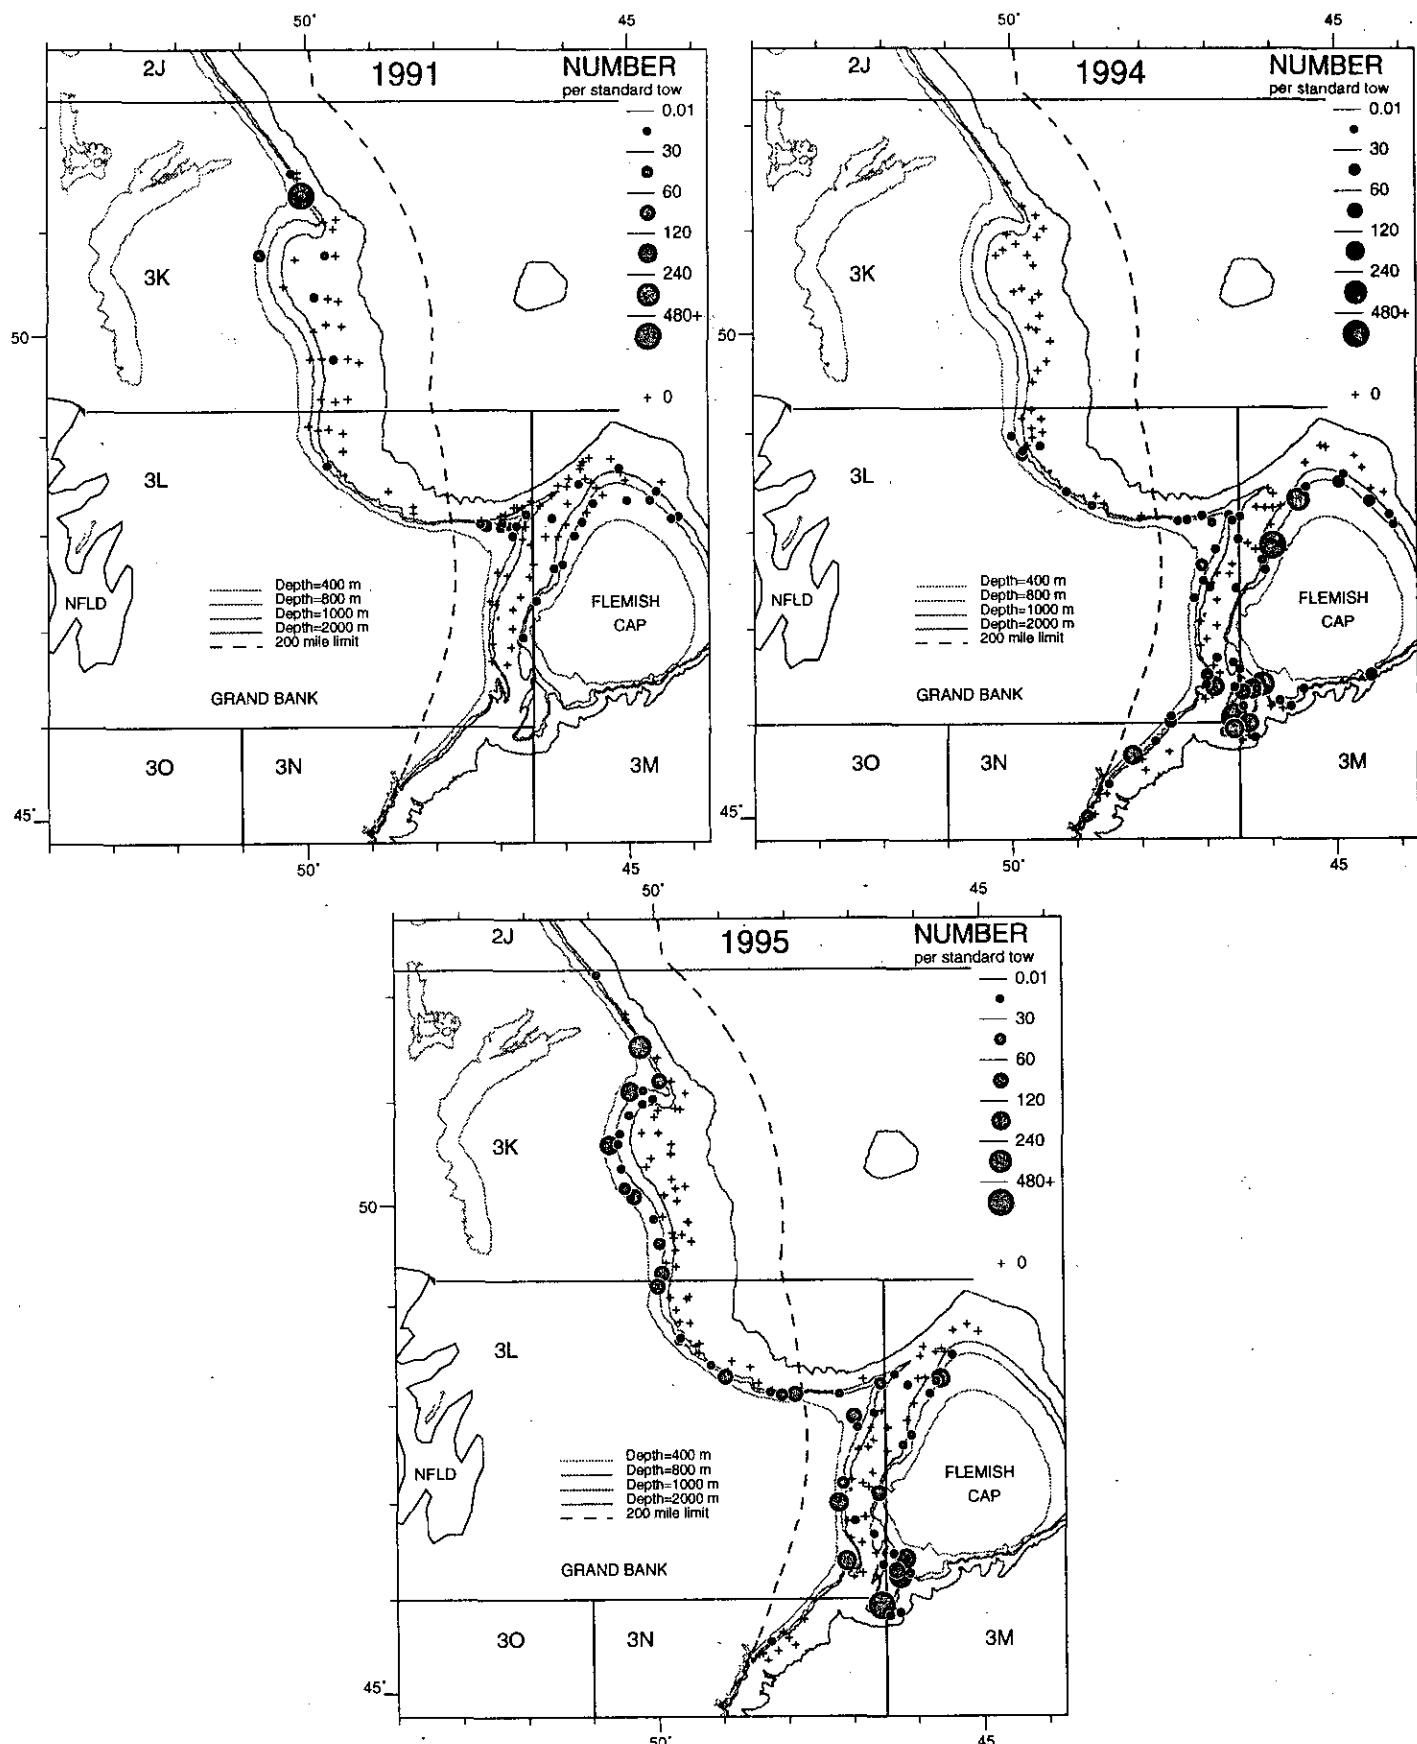

Fig. 8. Distribution of redfish catches from Greenland halibut directed Canadian surveys of NAFO Divisions 3KLMN from 1991-1995. Surveys were conducted by the Cape Adair (1991, 650 m - 1800 m), Zandvoort (1994, 750 m - 1500 m) and FRV Teleost (1995, 500 m - 1700 m). Circles represent catch number per standard tow (1.75 nautical miles). Dashed line represents division between the Canadian economic zone and the NAFO Regulatory area (east of line)

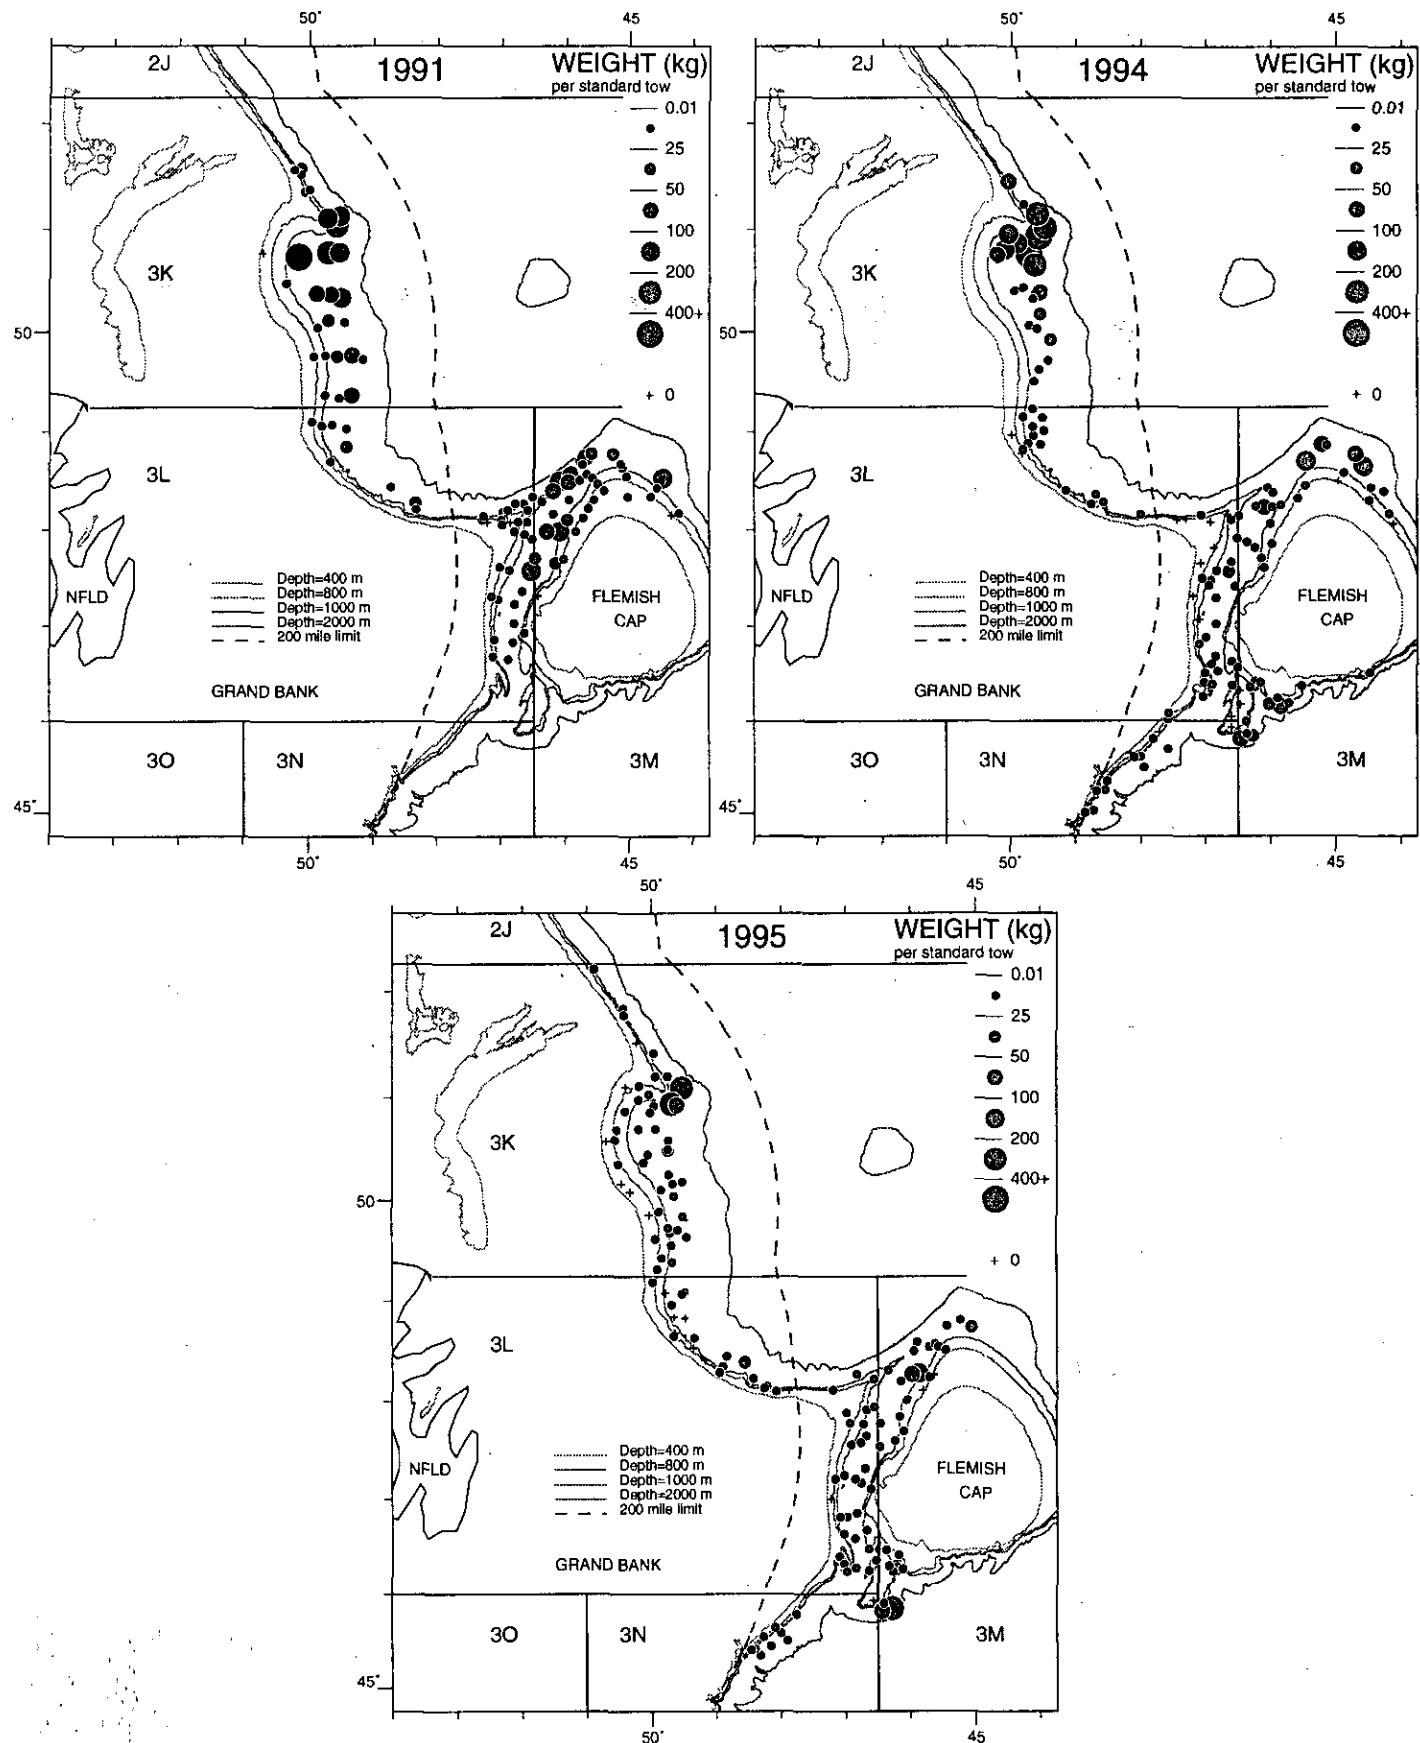

Fig. 9. Distribution of roundnose grenadier catches from Greenland halibut directed Canadian surveys of NAFO Divisions 3KLMN from 1991-1995. Surveys were conducted by the Cape Adair (1991, 650 m - 1800 m), Zandvoort (1994, 750 m - 1500 m) and FRV Teleost (1995, 500 m - 1700 m). Circles represent catch weight (kg) per standard tow (1.75 nautical miles). Dashed line represents division between the Canadian economic zone and the NAFO Regulatory area (east of line)

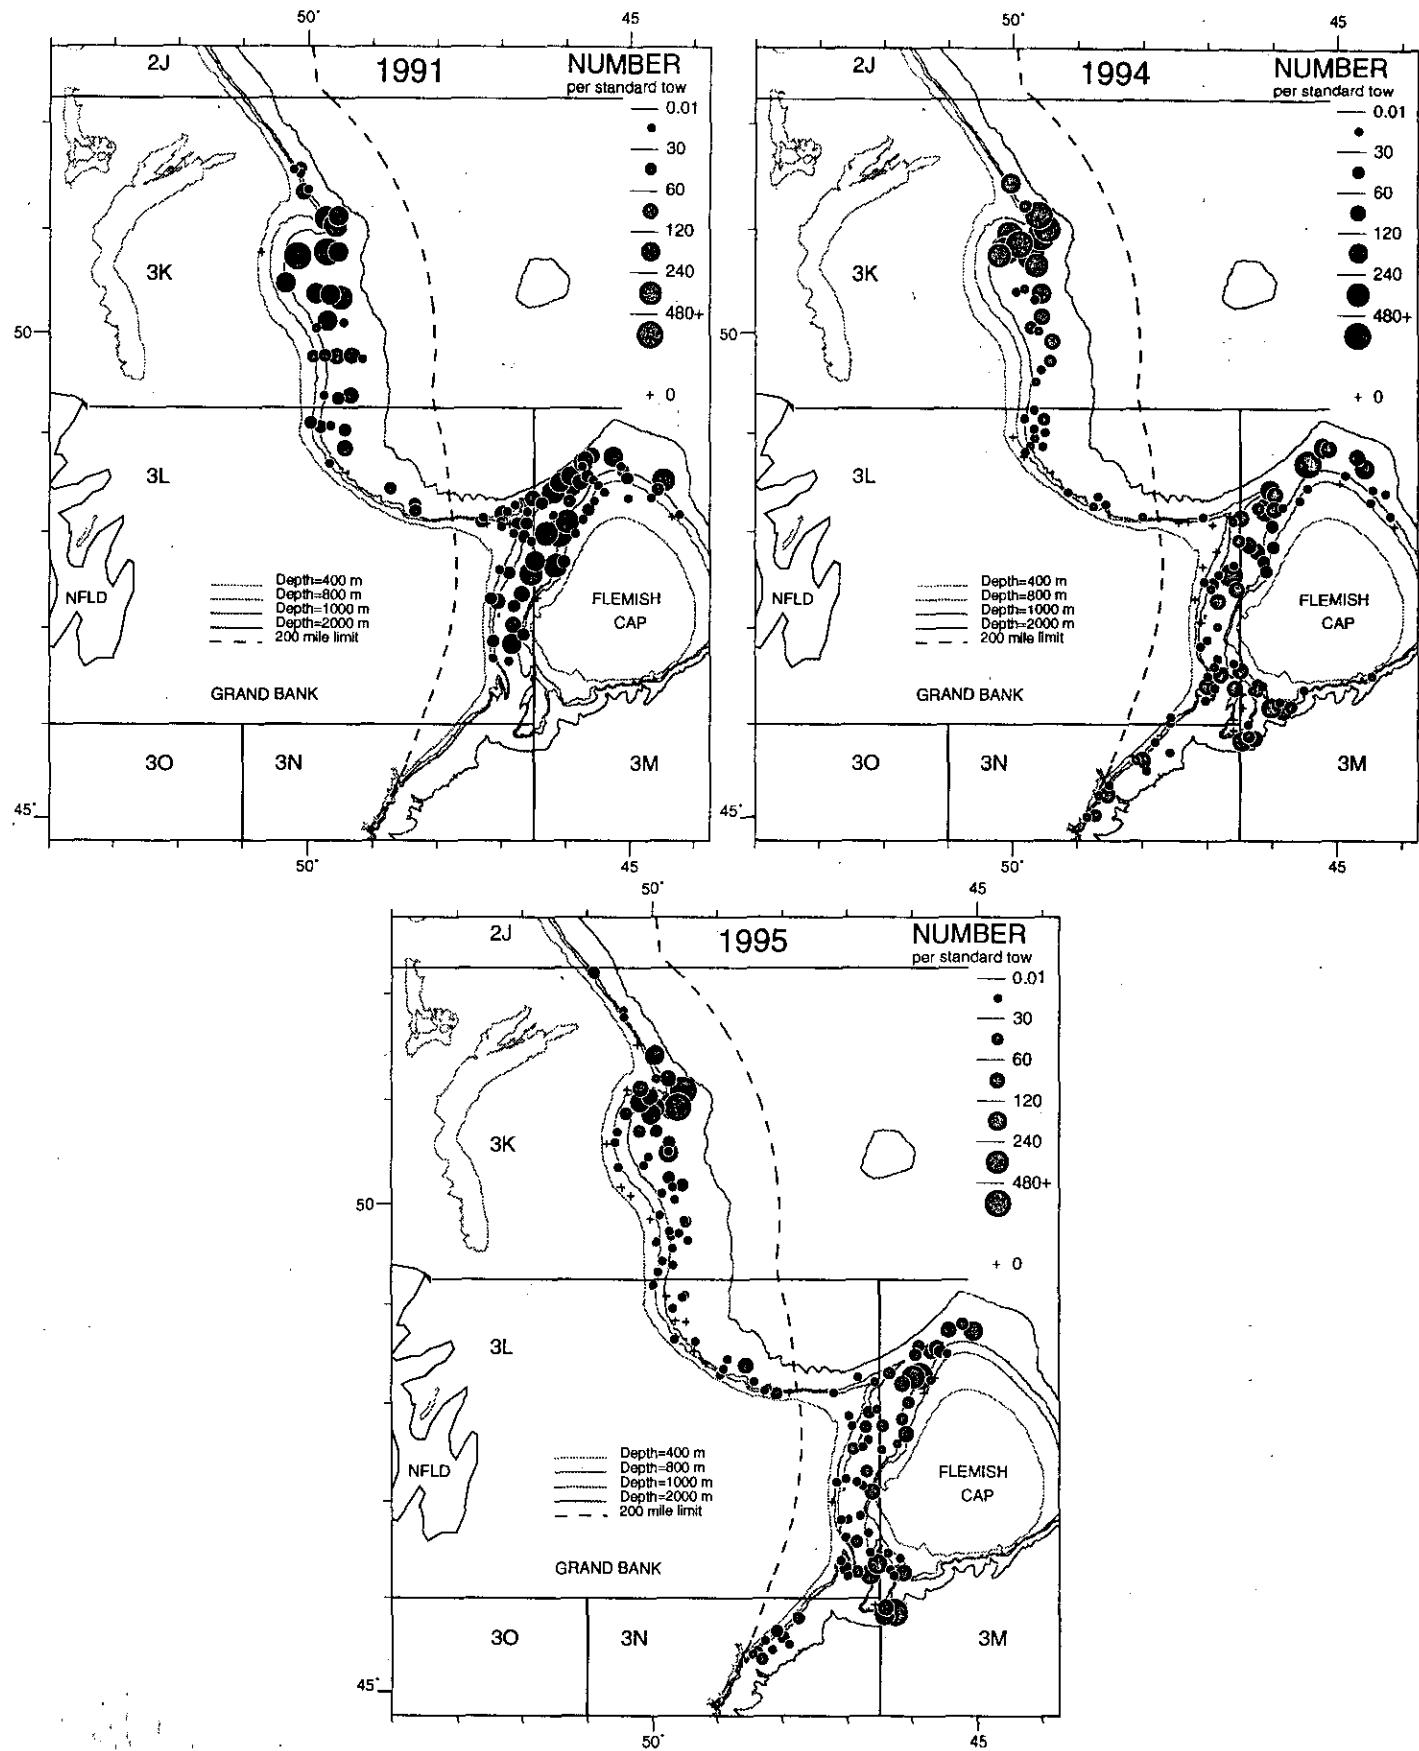

Fig. 10. Distribution of roundnose grenadier catches from Greenland halibut directed Canadian surveys of NAFO Divisions 3KLMN from 1991-1995. Surveys were conducted by the Cape Adair (1991, 650 m - 1800 m), Zandvoort (1994, 750 m - 1500 m) and FRV Teleost (1995, 500 m - 1700 m). Circles represent catch number per standard tow (1.75 nautical miles). Dashed line represents division between the Canadian economic zone and the NAFO Regulatory area (east of line).

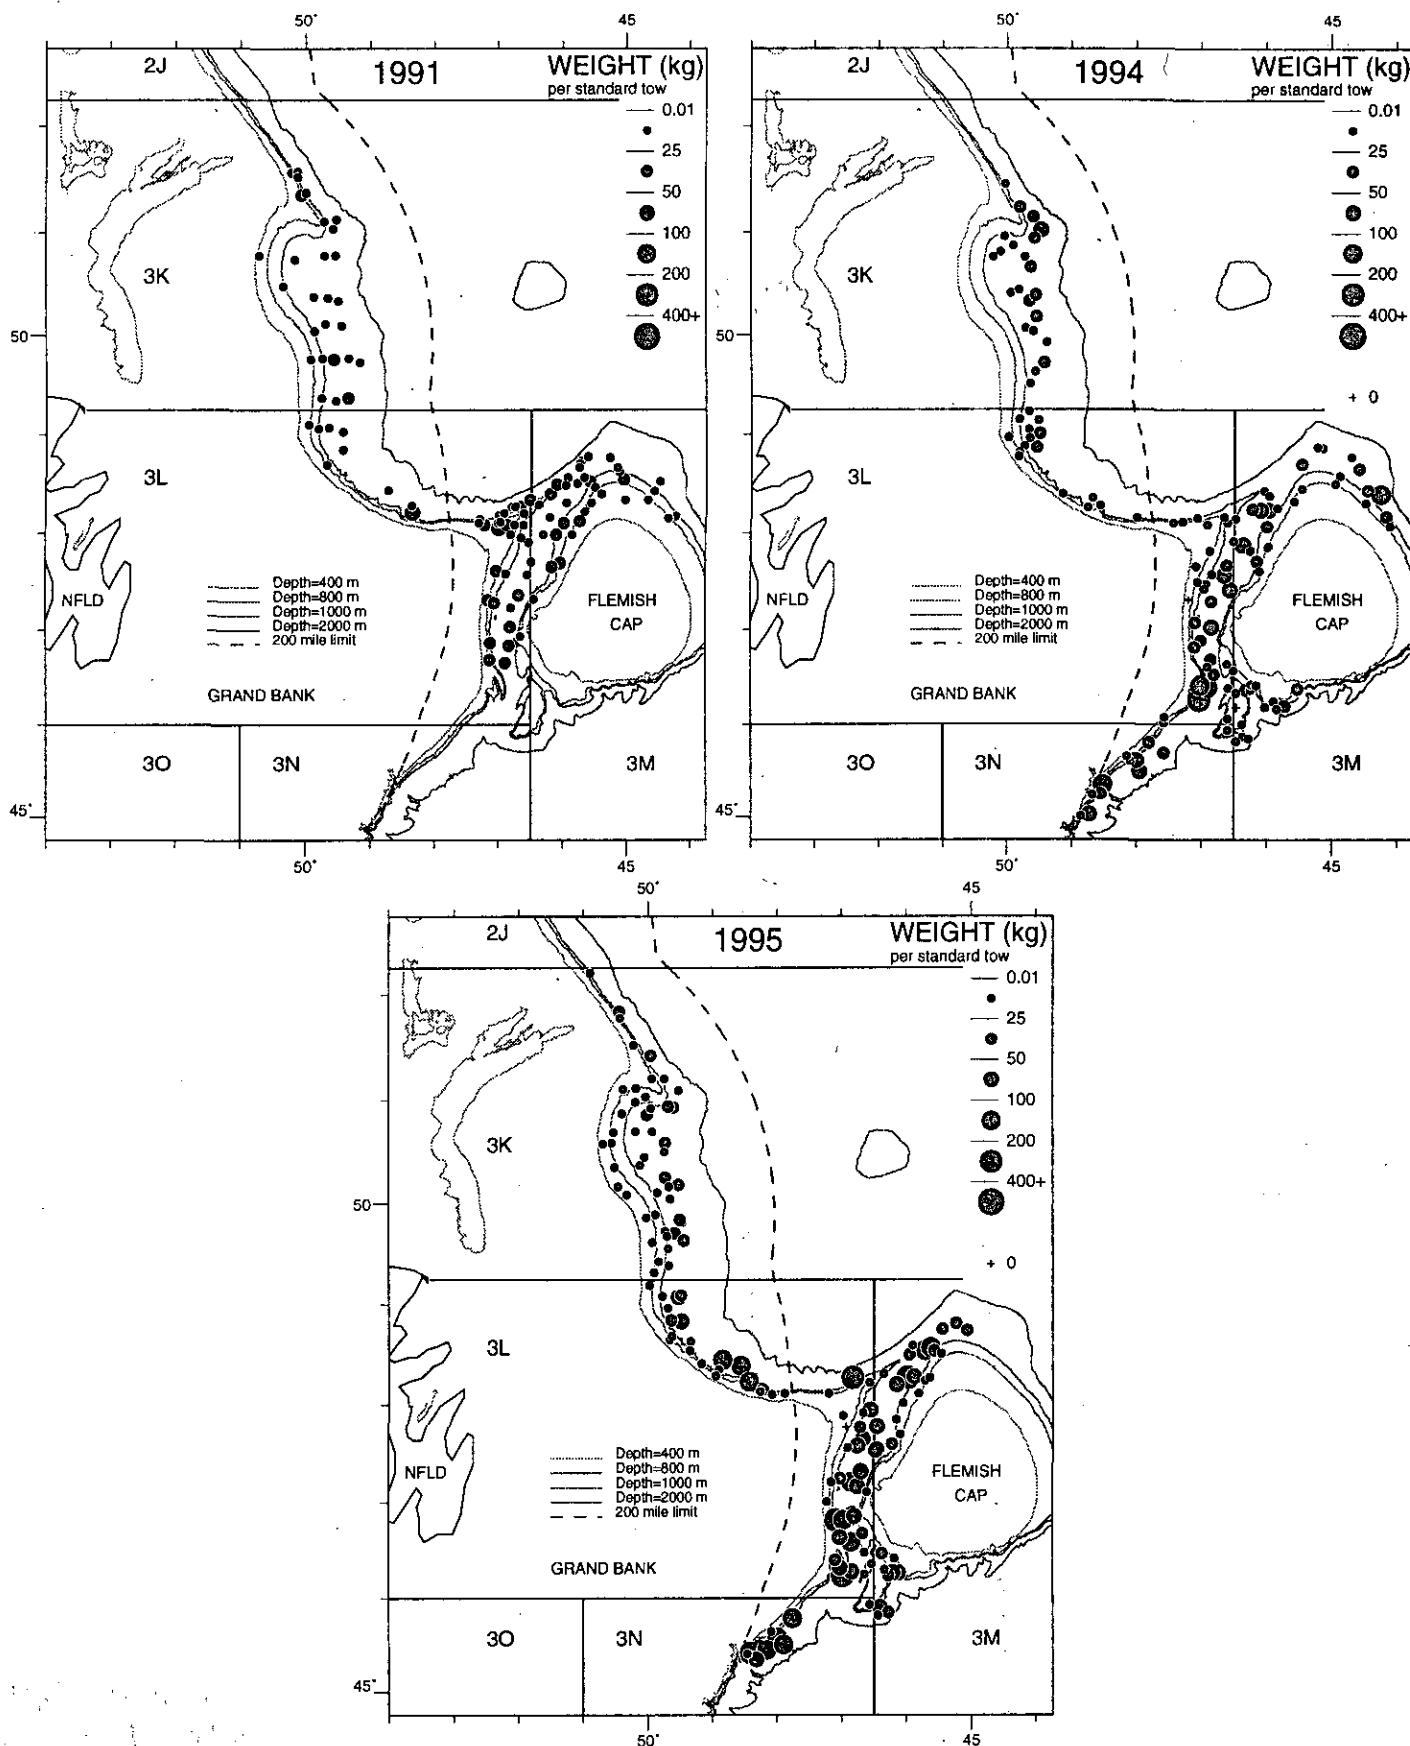

Fig. 11: Distribution of roughhead grenadier catches from Greenland halibut directed Canadian surveys of NAFO Divisions 3KLMN from 1991-1995. Surveys were conducted by the Cape Adair (1991, 650 m - 1800 m), Zandvoort (1994, 750 m - 1500 m) and FRV Teleost (1995, 500 m - 1700 m). Circles represent catch weight (kg) per standard tow (1.75 nautical miles). Dashed line represents division between the Canadian economic zone and the NAFO Regulatory area (east of line)

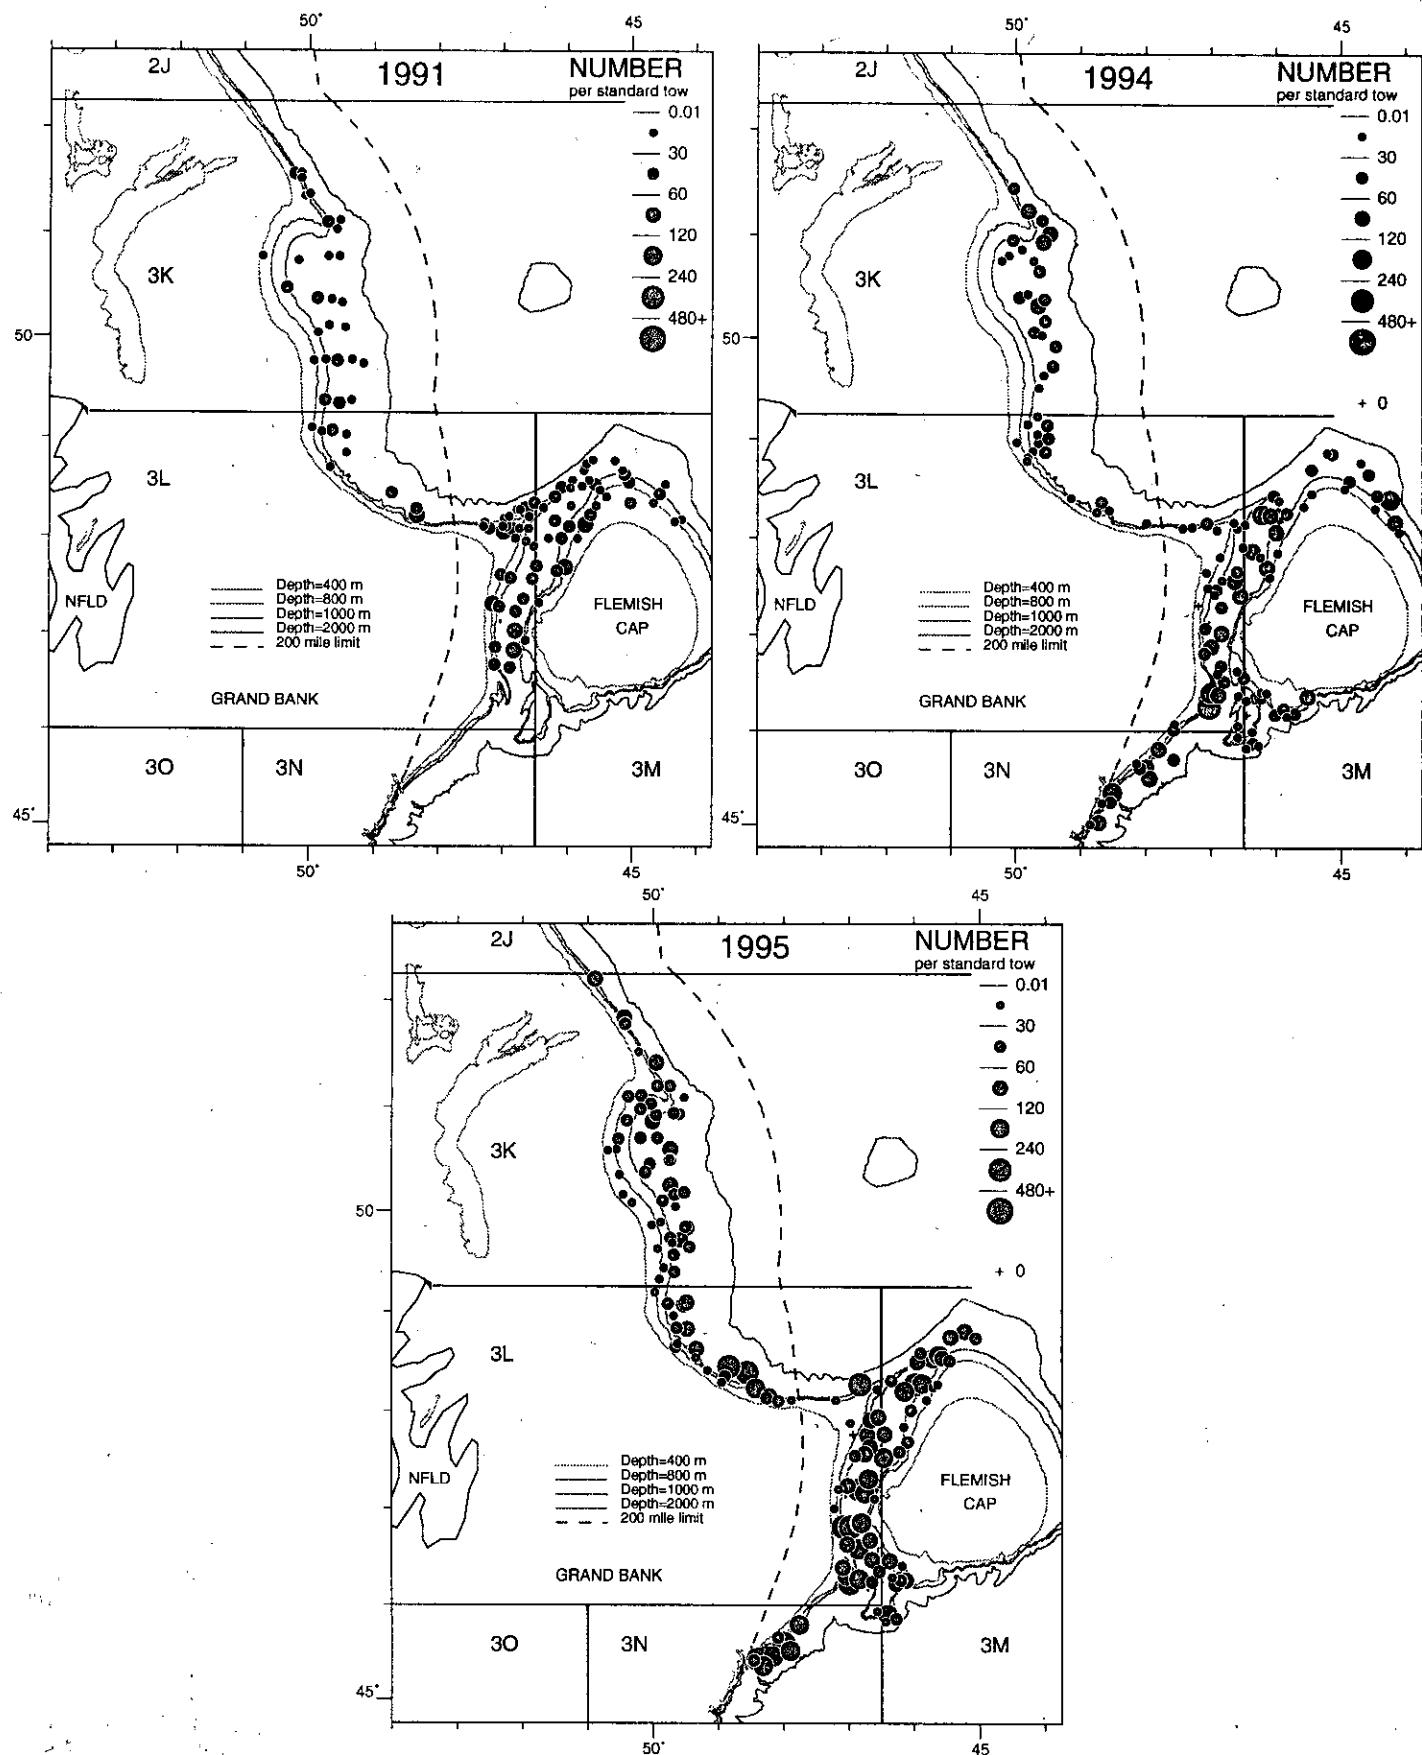

Fig. 12. Distribution of roughhead grenadier catches from Greenland halibut directed Canadian surveys of NAFO Divisions 3KLMN from 1991-1995. Surveys were conducted by the Cape Adair (1991, 650 m - 1800 m), Zandvoort (1994, 750 m - 1500 m) and FRV Teleost (1995, 500 m - 1700 m). Circles represent catch number per standard tow (1.75 nautical miles). Dashed line represents division between the Canadian economic zone and the NAFO Regulatory area (east of line)
