Extended survivors analysis was carried out in several ways. A number of trials indicated that whatever the formulation with regard to the tuning fleets used and the ages at which catchability were set, there was little difference in the fit of the model.

The diagnostics and output from the chosen run are presented below. Summary data are presented in Figures 1 and 2.

Catch data for 7 years, 1988 to 1994. Ages 1 to 8.

Fleet	First year	Last year	First age	Last age	Alpha	Beta
EU-SURV	1988	1994	1	7	0.5	0.6

Time series weights :

Tapered time weighting applied

Power = 3 over 20 years

Catchability analysis :

Catchability dependent on stock size for ages < 3

Regression type = C

Minimum of 5 points used for regression

Survivor estimates shrunk to the population mean for ages < 3

Catchability independent of age for ages >= 3

Terminal population estimation :

Survivor estimates shrunk towards the mean F
of the final 5 years or the 5 oldest ages.

S.E. of the mean to which the estimates are shrunk = .500

Minimum standard error for population
estimates derived from each fleet = .300

Prior weighting not applied

Tuning converged after 12 iterations
