SCIENTIFIC COUNCIL MEETING - NOVEMBER 1995

**The Catch Statistics of the Shrimp Fishery (*Pandalus borealis*) in the Denmark Strait in the Years 1980-1995**

by

U. Skúladóttir  
Marine Research Institute, Skúlagata 4  
P. O. Box 1390, 121 Reykjavík, Iceland

Abstract

In this paper detailed data on the catch, effort and CPUE from the shrimp fishery in the Denmark Strait for all countries in the years 1989 to 1995 are shown. Total effort and mean CPUE of all countries combined has been calculated using the figures for nominal catch for every country going as far back as 1978. It is considered here that the shrimp stock is the same on both sides of the midline between Iceland and Greenland in the so-called north and east area. The so-called middle and south areas may represent different stocks so the data coming from those will be kept separate from the north at present.

The catch rates in the traditional north and east area have been low for a number of years, namely from 90 to 109 kg in the years 1989 through 1993. The catch rate has now risen to 158 kg/hour in 1994 and remained stable in 1995 at 156 kg/hour. Most marked was the change in CPUE in 1994 after the effort was directed more to the two new areas south 65°N.

The nominal catch was some 5 200 tons in 1995 in the north (and east) area and some 1 700 tons in the middle area and south area.

Introduction

Shrimp in fishable concentrations in the Denmark Strait area was first found in September 1976 but a fishery was first commenced in 1978 by Iceland and a year later the Norwegians started fishing in the area as well, and by 1980, Greenland, Denmark, Faroe Islands and France joined in. From then on the fishery was carried out by all these 6 countries. However France has not been fishing since 1991.

In this paper all data available on the catch, effort and the CPUE, are gathered by month for all countries and strata within each area and then combined for the years 1989-1995. Similar proceedings have been carried out for the previous years 1980-1988 (Skúladóttir, 1991).

By 1993 there are two new areas being fished south of 65°N. The south area was searched by Greenland in 1989 (Lehmann, 1990) and some concentrations of shrimp were found. After opening the redfish box in 1993 a fishery was started in the so-called middle area (Fig. 1). The data from these two new areas are kept separate from the north and east area throughout the paper.

## Material and Methods

For most of the catch there are logbook data which include catch and effort. The individual authors have also calculated the CPUE by dividing the catch per month (in kg) by the corresponding effort (in trawling hours). In order to assess the overall CPUE per every half year, all the effort in the period January to June was summed. Then only the catches that correspond to stated effort are summed by every half year. The subtotal sum of the catch is divided by the subtotal sum of effort to get the CPUE per every half year. In order to assess the total effort exerted by each country in the area, the nominal catch per month is summed by every half year. The nominal catch is often higher than the catch reported in logbooks. Therefore the effort was corrected by every half year by dividing the nominal total catch by the CPUE of the same half year. It has been assumed here that the gear and the efficiency of all vessels of a country is more like that of the ones not reporting of the same country than that of other countries. Therefore the effort was first corrected by individual countries.

## Results and Discussion

The effort, catch and nominal catch as well as the calculated CPUE are presented in tables 1 to 6 for the six countries for the north area, including the east area which is only fished by Iceland (Table 4) namely north of 65°N. The data for the middle and south areas combined, namely south of 65°N, are presented in tables 8 - 11.

For the first years the CPUE and effort was taken from the NAFO Scientific Council Reports 1980 and 1983 (Skúladóttir 1991). Later the CPUE and effort data were obtained from the scientists of the respective countries. For Norway, the data come from Smedstad and Torheim (1992) and later Smedstad, Kuhnle and Gilja (personal communication). For France the data come from Bertrand, Battaglia and Poulard (personal communication). The nominal catch data were obtained from Carlsson and Kanneworff (1992) and now from Siegstad and Carlsson (1994 and 1995).

Table 7 which has data for the north area for all countries by half years goes back to 1978. From table 7 it is notable that there is considerable variation in the CPUE of the different countries. This could be due to different gear sizes and the difference in power of the respective vessels. For the Icelandic vessels it is known that gear size was about 2400 meshes (circumference) for many years, but increased in 1993 to about 2700 meshes. The mean size of trawl has gone down again for 1994 and 1995, being some 2100 and 2300 meshes respectively. There is also a fall in CPUE in the latter half of year 1995. However a second peak in catch rates can occur late in the year.

The yearly catch rate is calculated in table 12 where the half years are added together. The CPUEs have been falling gradually since the years 1980 and 1981 or from 245 kg per hour to 90 kg in 1991. In spite of doubling the effort there was little gain in addition to the 11 thousand tons fished in 1986. However by 1993 the effort has decreased considerably or from 11 thous. hours in 1989 to some 72 thous. hours in 1993. In 1994 there is the most dramatic drop in effort or down to 31 thous. hours. The catch in the traditional area has gone down drastically as well at the same time as the new areas come into use. The CPUE has now increased to 158 kg in 1994 in the traditional area, and is about the same in 1995 namely 156 kg.

Table 13 contains the logbook data gathered together for the four countries for the middle and south area combined in 1993 through 1995. Apart from the huge CPUE that the Faroe Islands and Greenland report in the second half of 1993, 1381 kg per trawling hour with only little effort spent, the CPUEs are not much higher than they were in the beginning of the eighties in the traditional north area as average annual CPUE. The mean CPUE was 164 kg, 268 kg and 214 kg/hour in the years 1993, 1994 and 1995 respectively (table 14).

The total catch is listed in Table 15 as well as advised TAC by the Scientific Council of NAFO, by years. Through the years the effective TAC by Greenlandic authorities has usually been moderate and similar to the advised TAC. However from the year 1990 onwards the effective TACs have been far too high. Those unrealistic TACs of some 13 000 to 14 500 tons have never been reached in Denmark Strait not even with the additional catch east of the midline which is not included in the TAC set by

Greenland. In the north area the yearly catch has been gradually falling as CPUE and availability decreased. Moreover in 1993 through 1995 much effort was directed towards the new areas, south of 65° N. The total catch was only 4 872 tons in the traditional area in 1994 as compared to 6 503 tons in 1993. In the middle and south area 1 191 tons and some 4950 tons were fished in the years 1993 and 1994 respectively. In 1995 there appears to be a increased fishery in the north area. The catch in the east area in 1995 is the lowest in 4 years as a result of heavy ice conditions. In the area altogether 7 694 tons were fished in 1993 and 9 822 tons in 1994. The provisional catch in 1995 for the months January-October is 6 907 tons.

#### Conclusion

The stock in the traditional area of Denmark Strait appears to have reached the stage in 1995 where stock level has reached a higher stable level than in the years 1989 to 1993 as judged by CPUE although not as high as that of the early eighties. The reduced annual removals from the shrimp stock in the north area of Denmark Strait appear to have had a beneficial influence on the state of stock. It is not certain if a connection exists between the northern area and the southern areas.
