

Serial No. N3084

NAFO SCR Doc. 98/83

SCIENTIFIC COUNCIL MEETING - SEPTEMBER 1998

**Biomass estimate, length and age distribution of the northern shrimp  
(*Pandalus borealis*) stock on Flemish Cap (NAFO Div. 3M) in July 1998  
and Faroese catches in 1997 and 1998**

Árni Nicolaisen  
*Fiskirannsókhárstovan, Fisheries Laboratory of the Faroes*  
Nóatún, P.O.Box 3051, Tórshavn, Faroe Islands

*Catches and effort*

In 1997 five double trawl and one single trawl and in 1998 five double trawl and two single trawl Faroese shrimp vessels were engaged in the shrimp fishery on Flemish Cap (NAFO Div. 3M). Catch and effort by month for 1997 and 1998 (until week no. 34) are presented in Tab. 1. The data were originally recorded by week and subsequently transformed to months. A month that shared a week was allotted a value proportional to the number of days of the shared week in the month.

The catches were 7387 t and 6866 t in 1997 and 1998 (until week no. 34), respectively. The effort was 1250 days and 858 days in 1997 and 1998 (until week no. 34), respectively. The catches in the months March-July in 1998 are up 30% from the previous year. The effort for the months March-July in 1998 is down 1% from the previous year. The CPUE for the months March-July in 1998 is up 27% from the previous year. The higher CPUE values in 1998 compared to 1997 probably reflects either a larger stock biomass or increased availability, or both.

*Survey*

In 1996 the Faroese Government decided to assess the shrimp stock on Flemish Cap (NAFO Div. 3M) and these investigations continued in 1998. The first shrimp survey was carried out in June 1997 (Nicolaisen, 1997).

**Materials and methods**

*Biomass estimate.*

In July 1998 a total of 62 stations were selected in a stratified random trawl survey design (Fig. 1). The station were allotted to the strata proportional to strata area. Stations were in the depth range 100-300 fathoms. Tow duration was 60 minutes and towing went on both day and night. As in the survey in 1997 the Faroese commercial shrimp trawler R/T Høgífossur (4400HP) was used for the operation. A single Angmassalik 3000 shrimp trawl with 40mm meshsize in the codend and 22mm bar spacing in the sorting grade was used.

For each station the density was calculated (Fig. 2). The catch data were standardised by dividing the catches by area swept, i.e. length of tow times width of the trawl. The length of tow was calculated by multiplying towing time with the average towing speed. The width of the trawl was calculated as the average distance between the doors as measured by an acoustic distance measuring devices (Scanmar). The average density values were calculated for each strata and multiplied with the strata area and summed for all strata to get the total biomass (Tab. 2).

*Length distribution*

At each station a sample of about 200 specimens of shrimp were taken from the unsorted catch and analysed onboard. The shrimps were measured to the nearest 0.5 mm using Vernier calipers and within length groups sorted by males and females (Rasmussen, 1953) and the females were further grouped into primiparous and multiparous (McCrary, 1971).

The length distribution from each sample was raised to the total shrimp catch and divided by area swept for each station to get abundance per unit area (density) at length. Mean density at length was calculated for each strata and multiplied by strata

area to get stock in numbers by strata. Stock in weight was calculated using a weight-length curve for shrimp in Div. 3M in the period 1993-95 (Nicolajsen, 1996).

#### *Age structure*

The length distribution from each sample was raised to the total shrimp catch from the station before summing with in sex and maturity groups. The three main sex and maturity groups: males, females with headroe with and with out sternal spines were seperated into age groups using the MIX software by MacDonnald and Pitcher (1979).

## **Results**

#### *Biomass estimate.*

The result of the total stock biomass calculations was 22804t (Tab. 2).

#### *Length distribution*

Age group 2 (at 14 mm) in 1997 constitutes as 3 yr (18.5 mm) in 1998 a large male component (Tabs. 3 and 4, Figs. 3 and 4). Age group 3 (18 mm) in 1997 as 4 yr (22.5 mm) in 1998 increasing the female component considerably. For the stock weight at length this development is even more evident (Tabs. 5 and 6, Figs. 5 and 6).

The stock in weight calculated for all strata for 1997 was 16461 t (Tab.5) compared with an area swept estimate of 16370 t (Nicolajsen, 1997) and for 1998 the calculated stock in weight was 23035 t (Tab. 6) compared with an area swept estimate of 22804 t (Tab. 2). The discrepancies are less then 1%.

Stock in numbers and biomass was more evenly distributed among the strata in 1998 compared to 1997 (Figs. 7 and 8). Mean weight of shrimp in the stock rose from 4.6 g to 5.9 g from 1997 to 1998.

#### *Age structure*

The length distribution by sex and maturity are shown in Tabs. 8 and 9 and Figs. 9 and 10 for 1997 and 1998. Codes used for sex and maturity used in the tables are shown in Tab. 7. Age distribution is shown in Tabs. 10 and 11 and Figs. 11 and 12 for 1997 and 1998.

## **Discussion**

#### *Biomass estimate.*

The stock biomass is 39% higher than the 16370t area swept result based on last years Faroese shrimp survey (Nicolajsen, 1997). The trend in these results are in accordance with the trend in catch rates in the Faroese shrimp fleet. Parsons *et.al.* (1997), based on a research trawl survey in September-October 1996, calculated the biomass with spatial analysis software to about 21500t.
