SCIENTIFIC COUNCIL MEETING – JUNE 2002

Abundance, Biomass and Population Structure for American Plaice from the Surveys Conducted
by Spain in the NAFO Regulatory Area of Divisions 3NO, 1995-2001

by

D. González Troncoso, X. Paz and Esther Román.

Instituto Español de Oceanografía,
P.O. Box 1552. Vigo, Spain.

Abstract

Since 1995, a stratified random spring bottom trawl survey in the NAFO Regulatory Area of Div. 3NO was conducted by Spain. The depth strata surveyed was extended to 1464 m. The main propose of the surveys was obtain abundance and biomass indices for the commercial species in the area. Following the recommendations of the 2000 Scientific Council Meeting, the entire series of abundance and biomass for American plaice are presented for the period 1995-2001. The indices calculated from the survey series shows a general increasing in the American plaice abundance and biomass in this period, and an important recruitment in the area in last years; this data suggest a recuperation of the stock.

Material and Methods

Survey design and gear used

The surveys on NAFO Regulatory Area of Div. 3NO was initiated by Spain in 1995. The surveys were carried out in spring (May), on board the Spanish vessel *C/V Playa de Menduiña* (338 GT and 800 HP) using bottom trawl net type *Pedreira*. The main specifications and geometry of this gear, as the rigging profile and the net plan, and a sheet with the resume of the main technical data of the survey are described in previous paper (Durán Muñoz *et. al.*, 2001). In the Table 1 are presented the number of valid tows, the depth strata covered and the dates of the survey series. In the period 1998-2001, the surveyed depth strata were the same (extended to 1464 m), more deeper than in the previous surveys, as show in the cited Table. The survey area was stratified following the standard stratification schemes (Bishop, 1994). Sets were allocated to strata proportionally to their size, with a minimum of two planned hauls per stratum and the trawl positions were chosen at random (Doubleday, 1981). Biomass and abundance indices were calculated by the swept area method (Cochram, 1997), assuming catchability factor of 1. The catch from each haul was sorted by species and weighed. Samples of American plaice were measured at random to the total length at cm below. Length distribution estimated from catches is presented for the period 1995-2001.

Stratified mean catches of American plaice

The mean catch is calculated by stratum by the following formula:

$$\bar{Y}_i = \sum_{j=1}^T \frac{y_j}{T}, i=1, \dots, h$$

where: y_j is the catch by haul in the stratum
 T is the number of hauls in the stratum
 h is the total number of strata

and the stratified mean catch by stratum is obtained as follow:

$$Y_i = \bar{Y}_i n_i, i=1, \dots, h$$

where: n_i is the area of the stratum i , $i=1, \dots, h$

Then the total stratified mean catch by year is calculated according to the formula:

$$\bar{Y} = \sum_{i=1}^h \frac{Y_i}{N}$$

where: $N = \sum_{i=1}^h n_i$ is the total area by year

Results

Catches of American plaice

The American plaice mean catches by stratum are presented in Table 2, included swept area, number of hauls and SD. The stratified mean catches of American plaice are presented in Table 3. Data from year 1995 are added, although in that year a few sets were made, so it is not representative. The American plaice indices show an increasing year by year, specially since 1998 (Fig. 1), although in 2001 it decreased in relation to 2000, but is higher than in 1999. The decreasing in 1997 value should be related to changes in the American plaice distribution.

Abundance and Biomass of American plaice

Following the recommendations of the 2000 Scientific Council Meeting, the entire time series (1995-2001) of abundance and biomass estimates of American plaice are presented (updated) in Table 4 and Table 5, respectively. The abundance Table show an increasing in the survey estimates through the studied period (Fig. 2), and quit the same occurs to biomass (Fig. 3), although in 2001 there was a decreasing with regard to 2000, as in mean catches. It shows that although the number of individual has increased, its weight has fell.

Presence of juveniles of American plaice

The length distribution of American plaice for the period 1995-2001 is shown in Table 6 and Table 7, and in figure 4 and Fig. 5 we can see its evolution along the years. The presence of juveniles (length ≤ 22 cm.) is increasing in the last years. The evolution of males and females is almost the same in the period 1999-2001 (Fig. 5). The high presence of juvenile individuals indicates the recruitment of a new class-year with a size higher than last years average. The increase of this new class-year may contribute to the recovery of the stock. It would be necessary other studies to determinate the size and the quantitative importance of this year-class.

Therefore, it suggests a recuperation of the American plaice. Against what NAFO reports said, our data of length of 2001 indicates a high number of recruits, even highest than the number of adults.

The data analysed from American plaice suggested the beginning of the rebuilding of this resource in the surveyed area.
