## SCIENTIFIC COUNCIL MEETING – JUNE 2004

Thorny Skate Indices from the Spanish Surveys Conducted in the NAFO Regulatory  
Area of Divisions 3NO, 1995-2003

by

Diana González Troncoso

Instituto Español de Oceanografía,  
P.O. Box 1552. Vigo, Spain.

### Abstract

Since 1995, a stratified random spring bottom trawl survey in the NAFO Regulatory Area of Div. 3NO was conducted by Spain. In 2001, the trawl vessel was replaced; so, the time series indices were transformed. The transformed entire series of mean catches, abundance and biomass for Thorny skate are presented for the period 1995-2000, and the length distribution for the period 1997-2000, and the no-transformed data for the years 2001-2003. The standard deviation are shown for abundance and biomass. The summed abundance and biomass based on conversion of the length frequencies are presented and compared to the estimates from the method used to convert the CPUE. A decreasing in Thorny skate abundance and biomass is observed in last years (2001-2003).

### Material and Methods

#### Survey design and gear used

The surveys on NAFO Regulatory Area of Div. 3NO was initiated by Spain in 1995. Until 2001, the surveys were carried out in spring (May), on board the Spanish vessel *C/V Playa de Menduiña* (338 GT and 800 HP) using bottom trawl net type *Pedreira*. Since that year, the *R/V Vizconde de Eza* replaced the *C/V Playa de Menduiña* as the research vessel for the survey, using bottom trawl net type *Campelen*. The main specifications and geometry of these gears, as the rigging profile and the net plan, and a sheet with the resume of the main technical data of the survey are described in previous paper (Walsh *et. al.*, 2001). In the Table 1 are presented the number of valid tows, the depth strata covered and the dates of the survey series. In the period 1998-2003, the surveyed depth strata was the same (extended to 1464 m). The survey area was stratified following the standard stratification schemes (Bishop, 1994). Set number was allocated to strata proportionally to their size, with a minimum of two planned hauls per stratum and the trawl positions were chosen at random (Doubleday, 1981).

Biomass and abundance indices were calculated by the swept area method (Cochran, 1997), assuming catchability factor of 1.

The catch from each haul was sorted by species and weighted. Random samples of Thorny skate were measured to the total length to the nearest lower cm. Length distribution estimated from catches is presented for the period 1997-2003.

*R/V Vizconde de Eza* had replaced *C/V Playa de Menduiña* in 2001 survey, so, in order to maintain the data series obtained since 1995, comparative fishing trials were conducted in spring 2001 to develop factors between the two fishing vessel and gear combinations. A series of 92 paired hauls was carried out, 90 of them were valid hauls. Mean

catch, stratified mean catch, abundance, biomass and their respective standard deviations, and length distribution, were transformed from C/V *Playa de Menduña* series to R/V *Vizconde de Eza* series.

#### Thorny skate stratified mean catches and SD

The mean catch ( $\bar{y}_i$ ) and the variance ( $Var_i$ ) are calculated by stratum by the following formulas:

$$\bar{y}_i = \sum_{j=1}^{T_i} \frac{y_j}{T_i}, \quad i = 1, \dots, h$$

$$Var_i = \sum_{j=1}^{T_i} \frac{(y_j - \bar{y}_i)^2}{T_i - 1}, \quad i = 1, \dots, h$$

where:

$y_j$  is the catch in haul  $j$

$T_i$  is the number of hauls in the stratum  $i$

$h$  is the total number of strata

and the stratified mean catch ( $\bar{y}_i^{str}$ ) and the stratified variance ( $Var_i^{str}$ ) by stratum are obtained as follow:

$$\bar{y}_i^{str} = \bar{y}_i n_i, \quad i = 1, \dots, h$$

$$Var_i^{str} = Var_i \frac{n_i^2}{T_i}, \quad i = 1, \dots, h$$

where:

$n_i$  is the area of the stratum  $i$ ,  $i = 1, \dots, h$

Then the total stratified mean catch ( $\bar{y}$ ) and the variance ( $Var$ ) by year are calculated according to the formulas:

$$\bar{Y} = \sum_{i=1}^h \frac{\bar{y}_i^{str}}{N}$$

$$Var = \sum_{i=1}^h \frac{Var_i^{str}}{N^2}$$

where:

$$N = \sum_{i=1}^h n_i \text{ is the total area by year}$$

The stratified standard deviation (SD) by year is calculated as the square root of the stratified variance by year.

#### Conversion factors

To convert data series it was necessary to calculate the factor power correction (FPC), typically estimated by use of catch per unit of effort (CPUE) observations for the two vessels. In this case, a multiplicative model solved by generalized method by haul was adjusted to convert mean catch, abundance and biomass. Although there are many

models to convert the CPUE, we choose one of them that has less error (Wilderbuer *et al.*, 1998, González Troncoso and Paz, 2003).

Robson (1966) proposed the following multiplicative model to establish the relationship between the CPUEs for the two ships:

$$CPUE_{ij} = e^{\mu + t_i + h_j + \varepsilon_{ij}}$$

where:

$t_i$  is the effect of the ship  $i$ ,  $i = 1, 2$

$h_j$  is the effect of the haul  $j$ ,  $j = 1, \dots, 90$

$\mu$  is the model parameter

$\varepsilon$  is the model error

A logarithmic transformation is performed in order to obtain a linear expression:

$$\ln(CPUE_{ij}) = \mu + t_i + h_j + \varepsilon_{ij}$$

This equation was adjusted by generalized linear regression assuming the following restriction necessary to estimate all parameters:

$$\sum_{i=1}^2 t_i = 0 \Rightarrow t_1 = t = -t_2$$

giving the following estimation of the FPC (Sissenwine and Bowman, 1978):

$$FPC = \frac{\overline{CPUE}_2}{\overline{CPUE}_1} = e^{2t(1+0.5s^2)} \quad (1)$$

where  $s^2$  is the variance obtained in the estimate of  $t$ .

This model was applied to convert mean catches and biomass. To convert abundance, we used the same formula but with abundance per unit of effort, instead of CPUE.

In the other hand, to convert the length distribution, the following multiplicative model, proposed by Warren (1997) was adjusted:

$$Ratio = \alpha l^\beta e^{\delta l} \quad (2)$$

where:

$$Ratio = \frac{Campelen\ Catch}{Pedreira\ Catch} \text{ by length}$$

$l$  is the length

$\alpha$ ,  $\beta$  and  $\delta$  are the estimated parameters.

For more details, see Paz *et al.* (2002).

We use, in all cases, only the hauls in which both vessels had non zero catch.

Following the recommendations of the 2003 Scientific Council Meeting, abundance and biomass were obtained from the two methods and compared. For obtained the biomass from the length distribution, we use the following formula:

$$W = a(l + 0.5)^b N$$

where:

$W$  = weight

$l$  = length

$N$  = number

#### Data series

For 1995-2000, transformed C/V *Playa de Menduíña* data series are presented. For 2002 and 2003, original R/V *Vizconde de Eza* data series are presented. In 2001, the deeper strata was not surveyed by the calibration experience. As the objective is to have data in all the strata surveyed last years, to obtain the more annual homogeneity possible in the series, in the no surveyed strata by the R/V *Vizconde de Eza* the transformed C/V *Playa de Menduíña* data were put. This was made to mean catch, stratified mean catch, abundance and biomass. In this way, in the strata surveyed the original R/V *Vizconde de Eza* data are presented and in the strata not surveyed the transformed C/V *Playa de Menduíña* are offered.

The method to convert the indices from the length distribution has no accurate variance. Besides this, as the fit is very poor in the extreme data, we must apply another parameters for the extreme lengths, and the cut points are choosing without objective criterion. Because of that, we do not consider this method as the best one for estimating the biomass indices.

## Results

#### Thorny skate Mean Catches

To convert mean catches, the CPUE was adjusted in model (1), giving the  $FPC_{bio} = 0.24610793$ .

The Thorny skate mean catches by stratum are presented in Table 2, included swept area, number of hauls and SD. Thorny skate stratified mean catches and its SD are presented in Table 3. Data from year 1995 are added, although in that year a few sets were made, so it is not representative. The Thorny skate indices show a general increasing until 2000, and a decreasing in last years (Fig. 1).

#### Thorny skate Biomass

The entire time series (1995-2003) of biomass and their SD estimates of Thorny skate are presented (updated) in Table 4. The biomass presents the same trend as mean catches (Fig. 2).

To convert biomass, the CPUE was adjusted in model (1), giving the  $FPC_{bio} = 0.24610793$ . Besides the transformed biomass series, we present the biomass obtained from the transformed length distribution. Parameters  $a$  and  $b$  are presented in Table 5, and in Table 4 we present the comparison between the two indices. The trend is not the same in both series: since in the MCG series we can see a decreasing since 2001, in the length series we only can see the decreasing last year (Fig. 3).

#### Thorny skate Abundance

As in biomass, the entire time series (1995-2003) of abundance and their SD estimates of Thorny skate are presented (updated) in Table 6. The abundance table shows an increasing in the survey estimates until 2000, and a decreasing since that year (Fig. 4).

To convert abundance, the abundance per unit of effort was adjusted in model (1), giving the  $FPC_{ab} = 0.22950685$ . Besides the transformed abundance series, we present the abundance obtained summing the transformed length distribution. In Table 6 we present the comparison between the two series indices. The trend is not the same in both series: since in the MCG series we can see a decreasing in the year 2001, in the length series this decreasing has not been observed (Fig. 5).

#### Thorny skate Length Distribution

The result of the model proposed by Warren (2) for Thorny skate was the following:

$$\ln(\text{Ratio}) = \exp(4.5402 - 2.71751\ln(l) + 0.0749l)$$

Figure 6 shows the ratios and their fit. In this figure, we observed that, under 28 cm, the fit is very poor, so another conversion factor is applied for these values. So, two length classes are formed as follow (cf = conversion factor):

For  $l \leq 28$ : cf = 0.2114

For  $l \geq 29$ : cf =  $\exp(4.5402 - 2.71751\ln(l) + 0.0749l)$

In Table 7 is shown Thorny skate length distribution per thousand, besides the sampled size and its catch for the period 1997-2003. For years 1995 and 1996, we have not length data. In Figure 7 we can see the length distribution evolution along the years. It can be seen a quite presence of recruitment in 2002, that has not occurred last year.

$$(**) SD = \frac{\sum (x_i - \bar{x})}{n-1}$$

**TABLE 3.-** Stratified mean catches (Kg) by stratum and year and SD by year of Thorny skate (1995-2003). n.s. means stratum not surveyed. 1995-2000 data are transformed C/V *Playa de Mendoña* data (by FPC). 2001-2003 data are original from R/V *Vizconde de Eza*. In 2001, (\*) indicates transformed data from C/V *Playa de Mendoña*, and (\*\*) represent the original results of R/V *Vizconde de Eza* without the C/V *Playa de Mendoña* data.

**TABLE 7 (cont.).-** Thorny skate length distribution. Estimated numbers in frequency in %. Spanish Spring Survey on NAFO 3NO: 1997-2003. Indet. means indeterminate. 1997-2000 data are transformed C/V *Playa de Menduiña* data. 2001-2003 data are original R/V *Vizconde de Eza* data.  
(\*) indicates untransformed data.
