Stock Abundance Indices and Length Compositions of Demersal Redfish and Other
Finfish in NAFO Sub-area 1 and near bottom water temperature
derived from the German bottom trawl survey 1982-2005

Abstract

Survey abundance, biomass estimates and length compositions for golden and deep sea redfish ≥ 17 cm (*Sebastes marinus* and *S. mentella*), juvenile redfish <17 cm, American plaice (*Hippoglossoides platessoides*), Atlantic and spotted wolffish (*Anarhichas lupus* and *A. minor*) and thorny skate (*Raja radiata*) in Division 1D to 1F are presented. For golden redfish, American plaice and both wolffishes, stocks sizes have declined significantly until the early 1990s and remained at a low level since until 2000. Since then, abundances increased only slightly. For thorny skate, abundances increased in the early 1990s and for deep-sea redfish in the late 1990s. Both abundances decreased since then. All stocks considered are presently composed of small and mainly juvenile specimens except for spotted wolffish. Near bottom water temperature continued to be high (since 1996), the maximum of the time series was observed in 2003.

Introduction

This paper presents estimates of stock abundance and biomass indices disaggregated by length as derived from annual German groundfish surveys for golden and deep sea redfish ≥ 17 cm (*Sebastes marinus* and *S. mentella*), juvenile redfish <17 cm, American plaice (*Hippoglossoides platessoides*), Atlantic and spotted wolffish (*Anarhichas lupus* and *A. minor*) and thorny skate (*Raja radiata*). The surveys commenced in 1982 and represent the longest time series of quantitative information from the traditional fishing grounds off West Greenland south of 67° northern latitude. Environmental conditions are reflected as trends in near bottom water temperatures. The information is presented as an update of continued analyses of the survey results (Rätz, 1999; Rätz and Stransky, 2003.)

Materials and Methods

Abundance, biomass estimates and length structures were derived from annual groundfish surveys covering shelf areas and the continental slope off West Greenland. Surveys commenced in 1982 and were primarily designed for the assessment of cod. Because of favourable weather and ice conditions and to avoid spawning concentrations, autumn was chosen for the time of the surveys. These were carried out by the research vessel (R/V) WALTHER HERWIG (II) throughout most of the time period. In 1984 R/V ANTON DOHRN was used and she was replaced by the new R/V WALTHER HERWIG III since 1994, respectively.

The fishing gear used was a standardized 140-feet bottom trawl, its net frame rigged with heavy ground gear because of the rough nature of the fishing grounds. A small mesh liner (10 mm) was used inside the cod end. The horizontal distance between wing-ends was 25 m at 300 m depth, the vertical net opening being 4 m. In 1994, smaller Polyvalent doors (4.5 m^2 , 1 500 kg) were used for the first time to reduce net damages due to overspread caused by bigger doors (6 m^2 , 1 700 kg), which have been used earlier. All calculations of abundance and biomass indices were based on the 'swept area' method using 22 m horizontal net opening as trawl parameter, i. e. the constructional width specified by the manufacturer. The towing time was normally 30 min. at a speed of 4.5 knots. Trawl parameters are listed in Table 1. Hauls, which received net damage or became hang-up after less than 15 minutes, were rejected. Some hauls of the 1987 and 1988 surveys were also included although their towing time had been intentionally reduced to 10 minutes because of the expected large cod catches as observed from echo sounder traces.

Fish were identified to species or lowest taxonomic level and the catch in number and weight was recorded. Total fish lengths were measured to cm below.

The surveys were primarily designed for the assessment of cod. In order to reduce the error of abundance estimates, the subdivision of shelf areas and the continental slope into different geographic and depth strata was required due to a pronounced heterogeneity of cod distribution. The survey area was thus split into four geographic strata. Each stratum was itself subdivided into two depth strata covering the 0-200 m and 201-400 m zones. Figure 1 and Table 2 indicate the names of the 8 strata, their geographic boundaries, depth ranges and areas in nautical square miles (nm^2). All strata were limited at the 3 mile offshore line.

The applied strategy was to distribute the sampling effort according both to the stratum areas and to cod abundance. Consequently, fifty percent of the hauls were allocated proportionally to strata by stratum area while the other fifty percent were apportioned on the basis of a review of the historical mean cod abundance/ nm^2 , all hauls being randomly distributed within trawlable areas of the various strata. Non-trawlable areas were mainly located inshore. During 1982-2002, 1 697 successful sets were carried out, the numbers of valid sets by year and stratum being listed in Table 3. In 1995 and since 2001, the survey area off West Greenland was incompletely covered due to technical problems. Only 75% of the strata of West Greenland were covered in 2005. Figure 1 shows the positions of hauls conducted during the most recent survey.

Stratified abundance estimates were calculated from catch-per-tow data using the stratum areas as weighting factor (Cochran, 1953; Saville, 1977). Strata with less than five valid sets were rejected from the calculation. The coefficient of catchability was set arbitrarily at 1.0, implying that estimates are merely indices of abundance and biomass. Respective confidence intervals (CI) were set at the 95% level of significance of the stratified mean.

Near bottom water temperature was measured directly before or after a trawl haul by means of a CTD sonde. The annual stratified mean temperature was estimated in the same manner as applied for the fish abundance, i.e. through area weighting (Cochran, 1953; Saville, 1977).

Results

Figure 1 displays the coverage of the survey area by the geographical haul distribution in 2005. All abundance estimates in 1995 and since 2001 must be considered significantly underestimated as a result of the incomplete coverage of the survey area.

The abundance and biomass indices by stratum of *S. marinus* $>= 17 \text{ cm}$ is given in Table 3 and illustrated in Figure 2. The stock is indicated to be depleted since the early 1990s. Substantial recovery is though not apparent. The stock is mainly composed of golden redfish varying among 20-35 cm in body length, with a recently increased portion of fishes of 19-28 cm length (Fig. 3 and Table 4) indicated incoming year classes as could be derived from last years peak abundances of juveniles $< 17 \text{ cm}$.

Table 5 lists the abundance and biomass indices of *S. mentella* $>= 17 \text{ cm}$ by stratum, the values being presented in Fig. 4. Abundance peaked in 1996 and decreased since then. Opposite to 2004, the length distribution is bimodal

with modes at 30 cm and 17-20 cm. As for golden redfish, the latter indicates an incoming but less pronounced year class (Fig. 5 and Table 6). It must be noted, that the survey design hardly covers the distribution area of deep sea redfish, and the survey results should be carefully interpreted.

The abundance of juvenile redfish <17 cm *Sebastes* spp. has varied over a wide range since 1982. The recent index is among the lowest observed since 1982 (Fig. 6 and Table 7). The length composition revealed peaks at 6-7, 10-12 and 14-16 cm, an indication of sizes at ages 0, 1 and 2 in autumn (Fig. 7 and Table 8). The strong peak for age 0 in 2004 does not re-appear as age 1 in 2005.

Abundance and biomass of American plaice *Hippoglossoides platessoides* significantly declined since the late 1980s but increased slightly since 2002 (Fig. 8 and Table 9). Opposite to previous years when the stock predominantly was composed of small fish below 20 cm as illustrated in Figure 9 and listed in Table 10, the share of specimens 30 cm increased in 2005. The catchability of flatfish by the survey gear is considered poor but the time series seems to represent the stock development.

Atlantic wolfish *Anarhichas lupus* does not show a decrease in survey abundance but in biomass estimates, which were significantly lower in the 1990s (Fig. 10 and Table 11). That indicates that the stock then was mainly composed of small fish with low body weights. This indication is confirmed by the length distributions given in Figure 11 and Table 12 as fish below 35 cm are recently dominating the size composition of the stock.

The abundance and biomass of spotted wolfish *Anarhichas minor* decreased significantly since 1992 and remained low (Fig. 12 and Table 13). A slight increase is apparent since 2000. The size distribution is scattered as a result of low catch rates and high variation in body length (Fig. 13 and Table 14).

Both abundance and biomass indices of thorny skate *Raja radiata* are recently very low compared to the values estimated during the 1980s and early 1990s (Fig. 14 and Table 15). Whereas the size composition was dominated by small fish below 25 cm body length in previous years (Fig. 15 and Table 16), the length distribution in 2005 was more even.

Trends in near bottom temperature means by stratum and stratified mean temperature are listed in Table 17 and shown in Fig. 16. They reveal that the warm conditions off West Greenland continued since 1996 with a maximum stratified mean temperature in 2003. The stratum mean temperatures show a significant depth effect, with the colder temperatures measured in the shallow strata (<200 m). Deeper strata are generally warmer by about 1-2°C.

Table 14. (continued)

Table 15. *Raja radiata*, abundance (1 000) and biomass (tons) for West Greenland by stratum and total, 1982-2005.
 Confidence intervals (CI) are given in per cent of the stratified mean at 95% level of significance.

Fig. 1. Stratification of the survey area as specified in Table 2, positions of hauls carried out off West Greenland in 2005.

Fig. 2. Abundance and biomass indices for *S. marinus* >=17 cm off West Greenland, 1982-2005. Respective values are listed in Table 3.

Fig. 3. Length disaggregated abundance indices for *S. marinus* ≥ 17 cm off West Greenland, 2002-2005. Respective values are listed in Table 4.

Fig. 4. Abundance and biomass indices for *S. mentella* ≥ 17 cm off West Greenland, 1982-2005. Respective values are listed in Table 5.

Fig. 5. Length disaggregated abundance indices for *S. mentella* ≥ 17 cm off West Greenland, 2002-2005. Respective values are listed in Table 6.

Fig. 6. Abundance and biomass indices for *Sebastes* spp. < 17 cm off West Greenland, 1982-2005. Respective values are listed in Table 7.

Fig. 7. Length disaggregated abundance indices for *Sebastes spp.* <17 cm off West Greenland, 2002-2005. Respective values are listed in Table 8.

Fig. 8. Abundance and biomass indices for *Hippoglossoides platessoides* off West Greenland, 1982-2005. Respective values are listed in Table 9.

Fig. 9. Length disaggregated abundance indices for *Hippoglossoides platessoides* off West Greenland, 2002-2005. Respective values are listed in Table 10.

Fig. 10. Abundance and biomass indices for *Anarhichas lupus* off West Greenland, 1982-2005. Respective values are listed in Table 11.

Fig. 11. Length disaggregated abundance indices for *Anarhichas lupus* off West Greenland, 2002-2005. Respective values are listed in Table 12.

Fig. 12. Abundance and biomass indices for *Anarhichas minor* off West Greenland, 1982-2005. Respective values are listed in Table 13.

Fig. 13. Length disaggregated abundance indices for *Anarhichas minor* off West Greenland, 2002-2005. Respective values are listed in Table 14.

Fig. 14. Abundance and biomass indices for *Raja radiata* off West Greenland, 1982-2005. Respective values are listed in Table 15.

Fig. 15. Length disaggregated abundance indices for *Raja radiata* off West Greenland, 2002-2005. Respective values are listed in Table 16.

Fig. 16 Stratum means of near bottom temperature ($^{\circ}\text{C}$) and stratified mean, 1982-2005. Respective values are listed in Table 17. Solid lines display trends in shallow strata (<200 m), dashed lines display trends in deep strata (>200 m),
