Abstract

Greenland halibut (*Reinhardtius hippoglossoides*) and American plaice (*Hippoglossoides platessoides*) indices from the bottom trawl survey that Spain carries out in spring since 1995 in div. 3NO of the NAFO Regulatory Area are presented. Biomass, length distribution and age distribution are presented since 1997, year in that the survey extended the depth strata. In 2001, the R/V *Vizconde de Eza* replaced the C/V *Playa de Mendoña* in the execution of the survey. We present the transformed to the R/V *Vizconde de Eza* series for the period 1997-2000, and the original obtained data for the period 2002-2006. In 2001, there are data from the two vessels. Greenland halibut biomass and abundance estimates present a decreasing trend since 1999. It seems not to be recuperation of the stock. In last years it can be seen a presence of juveniles, mainly in 2004, but the greatest lengths have failed. For American plaice we can see an increasing trend along the whole period, reaching a maximum in 2006. For this species, a good recruitment occurred in 2004.

Material and Methods

Since 1995, Spain carries out a spring-summer survey in the NAFO Regulatory Area of Div. 3NO on board the C/V *Playa de Mendoña* with a net trawl type *Pedreira*. In 2001, this vessel was replaced by the R/V *Vizconde de Eza*, using a trawl net type *Campelen*. To know more details about the technical specifications of the surveys, see Walsh *et al.*, 2001 and González Troncoso *et al.*, 2004.

The catch of each haul was sorted and weighted into species and a sample of each species was taken in order to measure the length distribution. For Greenland halibut and American plaice each individual of the sample was measured to the total length to the nearest lower cm. We present the indices for the period 1997-2006. In 1995 and 1996 only the less deeper strata were surveyed, so these years are not representative for these species, thus they are not included in the analysis.

In Table 1, we present the number of valid tows, the depth strata covered and the dates of the survey series (1997-2006).

For each species, all the indices are presented transformed until 2000 and no-transformed in the period 2002-2006. In the year 2001, there are data transformed from the former vessel with original data from the new vessel. To know more about the transformation, see González-Troncoso *et al.*, 2005 and González-Troncoso *et al.*, 2006. We present

per haul the mean catch, the stratified mean catch per tow and the biomass with their variance per year; the length distribution in number per haul stratified mean catches per length, sex and year; and by age the mean catches per tow age numbers with their mean length and mean weight. The age numbers were calculated starting from the stratified mean catches per haul length distribution applying the Age Length Key (ALK) for age-length keys. Weight at age was calculated by applying the length/weight relationship for each year to the mean length. For Greenland halibut, Spanish ALK was applied, but for American plaice we have no ALK yet, so we have used the Canadian ALK for this species (K. Dwyer and J. Morgan, com. pers.)

Results

Greenland halibut

Introduction

The Greenland halibut stock in Subarea and Div. 3KLMNO is considered to be part of a biological stock complex, which includes Subareas 0 and 1. Abundance and biomass indices were available from research vessel surveys by Canada in Div. 2J+3KLMNO (1978-2005), EU in Div. 3M (1988-2005) and EU-Spain in Div. 3NO (1995-2005). Commercial catch-at-age data were available from 1975-2005.

The exploitable biomass (age 5+) was reduced to low levels in 1995-97 due to very high catches and high fishing mortality. It increased during 1998-2000 due to greatly reduced catches, much lower fishing mortality and improved recruitment. However, increasingly higher catches and fishing mortality since then accompanied by scarce recruitment has caused a subsequent decline. The 2006 biomass estimate is the lowest in the series.

So, the exploitable biomass has been declining in recent years and is presently estimated to be at its lowest observed level. Recent recruitment has been below average, and fishing mortality has increased substantially in recent years, and is currently estimated as the highest in the time series (NAFO, 2006). Our results confirm these results presented by the Scientific Council last year.

Mean catches and Biomass

Table 2 shows the swept area, the tow number, the mean catches and their variance per haul and year to Greenland halibut. In Table 3 and Figure 1 we present the stratified mean catches per tow by stratum with the total variance per year. Table 4 and Figure 2 present the biomass per swept area per stratum and their total variance per year, as the biomass corresponding with the ages 5+ and 10+. In Table 5 we present the length-weight relationship parameters a and b .

The biomass of the Greenland halibut has decreased since the year 1999. At this moment, the biomass is much below the level of 1997. The lowest biomass value is in 2002. The stock seems not to recover. In 2006, we can see a reduce in the 10+ biomass of this species.

Length Distribution

Table 6 presents the stratified mean catches per haul length distribution for the Greenland halibut, by sex and year, with the number of samples in which there were length measures, the total number of individuals measured in these samples, the sampled catch and the range of lengths met, as the total catch of this species and the total hauls made in the survey. In Figures 3 and 4 we can follow the evolution along the years. We can follow a mode since 1997 until 2001, but since then no high new values appears. The highest recruitments were in 1997, 2001 and 2004. In 2006 the small individuals (around 12 cm) are the mode of the length distribution range.

Age numbers

We present the abundance at age per stratified mean catch by haul, by sex and by year in Table 7 and the total by year in Figure 5. Individuals between 0 and 20 years were caught in the period 1997-2006, and in last years (most since 2002) younger individuals were caught. Perhaps it can be due to the change of gear and/or vessel. We can

follow three conspicuous cohorts in our series, the 1994-1996 cohorts (ages 1, 2 and 3 in 1997). Cohorts from following years seem to be weaker than those ones, but more constant. And 2002-2003 cohorts appear to be quite strong, as we can see in recent years, specially 2003 one. This year the presence of all the ages classes is very weak, although there is a presence of individuals of age 1.

Mean length and mean weight

Mean length and weight at age by sex over time are presented in Tables 8 and 9, and shown in Figures 6 and 7. It seems that the greatest ages were increasing their mean length and weight until 2003, and falling in the youngest individuals. The mean length seems to be more stable than mean weight, at least for the youngest and the oldest individuals.

American plaice

Introduction

There was no directed fishing of American plaice in 1994 and there has been a moratorium from 1995. Even under moratorium, catches have increased substantially in recent years. Biomass and SSB are very low compared to historic levels. SSB declined to the lowest estimated level in 1994 and 1995. It has increased since then but still remains very low. There has been no good recruitment to the exploitable biomass since the mid-1980s (NAFO, 2006).

Mean catches and Biomass

American plaice haul mean catches by stratum are presented in Table 10, included swept area, number of hauls and SD. Stratified mean catches per tow by stratum and year and their SD are presented in Table 11.

The entire time series (1997-2006) of biomass and their SD estimates of American plaice are presented in Table 12. Estimated parameters a and b values of length-weight distribution are presented in Table 13.

The American plaice indices show a general increasing trend along the years, agree with the results from the Canadian surveys. We can see a decreasing in 2001 and 2002, and an increasing since then, reaching the maximum historical value in 2006 (Fig. 8 and 9).

Length Distribution

Table 14 and Figures 10 and 11 show the stratified mean catches per haul length distribution by sex and year, besides the sampled size and its catch, for the period 1997-2006. The data have been grouped two by two, so we present the data every two cm. In 2004 there is a great presence of juveniles (8 cm), and in 2005 the mode appears around 14 cm, following in 2006 with a mode of around 18 cm.

Age numbers

We present the abundance at age per stratified mean catch by haul in the Table 15 and Figure 12, by sex and year. The ALK is the Canadian one. This year there were no data enough to make a ALK, so we use for the year 2006 the sum of the ALKs for the period 1997-2005, separated by sexes. We can follow a cohort without problems since the year 2000, starting in individuals of 2 years old (1998 cohort), reaching 8 year old in 2006; a second cohort, weaker, can be followed since 1999, starting in 2 years old, too (1997 cohort). And more recently, a new cohort from the year 2002 (one year old in 2003), can be followed until 2006, reaching 4 years old.

Mean length and mean weight

Mean length and weight at age by sex over time are presented in Tables 16 and 17, and shown in Figures 13 and 14. The mean length is more or less stable in all ages, at least since the year 2002. The same occurs with the mean

weight, although with more variations. The major variations appears in the oldest ages studied: 13, 14 and 15+ years old individuals. From 1997 to 1999 a general decreasing in the two means is observed.

Acknowledgements

The authors are very grateful to Karen Dwyer and Joanne Morgan from the DFO of Newfoundland & Labrador, in St. John's, for letting us to use the Canadian ALK for American plaice.

$$SD = \sqrt{\frac{\sum (x_i - \bar{x})^2}{n-1}}$$

TABLE 2 (cont.).- Swept area, number of hauls and Greenland halibut mean catch (kg) and SD by stratum. Spanish Spring Surveys on NAFO Div. 3NO: 1997-2006. Swept area in square miles. n.s. means stratum not surveyed. 1997-2000 data are transformed C/V *Playa de Mendoña* data, and 2002-2006 data are original from R/V *Vizconde de Eza*. In 2001, there are data from the two vessels.

TABLE 4.- Survey estimates (by the swept area method) of Greenland halibut biomass (t) and SD by stratum and year on NAFO Div. 3NO. n.s. means stratum not surveyed. 1997-2000 data are transformed C/V *Playa de Menduiña* data. 2001-2006 data are original from R/V *Vizconde de Eza*. In 2001, there are data from the two vessels. The last two rows present the biomass corresponding to set of ages 5+ and 10+.
