SCIENTIFIC COUNCIL MEETING – JUNE 2008

Distribution and Abundance of Yellowtail Flounder (*Limanda ferruginea*) on the Grand Bank, NAFO Divisions 3LNO, from Canadian Bottom Trawl Survey Estimates from 1984-2007

by

D. Maddock Parsons and Bill Brodie

Abstract

Abundance and biomass indices of Grand Bank yellowtail flounder in NAFO Divisions 3LNO were derived from annual multi-species, random-stratified bottom trawl surveys conducted by Canada during the spring of 1984-2007 and during the fall from 1990 to 2007. The majority of the stock is found in depths less than 93 m and in Div. 3NO. Stock size and geographical range of yellowtail flounder declined from the mid-1980s to the mid-1990s, but recent surveys show the stock size has increased dramatically and has again expanded its northward range to re-occupy habitats on the northern Grand Bank. The 2006 spring estimate of biomass is the highest in the time series (504 kt) and the 2007 spring estimate (443 kt), is the second highest in the series. Biomass in the fall of 2006 is estimated to be 306 kt, a decrease from the 2005 value, but the 2007 estimate is the highest in the series at 482 kt.

Introduction

Annual multi-species, stratified-random bottom trawl surveys have been conducted by the Newfoundland region of the Canadian Dept of Fisheries and Oceans on the Grand Bank, in Div. 3LNO, during the spring (April-June) of each year since 1971. Since 1990, a second series of surveys has been carried out on the Grand Bank during the fall period, from October to December. However, since 1971 there have been two changes in survey gears and only one set of conversion factors has been developed for the 1984-1995 time series. Consequently only data from 1984 to 2007 will be presented here.

From both the spring and fall surveys, swept area abundance and biomass estimates are derived for yellowtail flounder (*Limanda ferruginea*) and serve as fishery-independent indices of stock size. Because catchability of the standard survey trawl is unknown and assumed to be <=1.0 (Walsh, 1996), the indices are considered to be relative estimates of stock size.

The purpose of this paper is to update the results of these annual surveys. The last review of the survey results in any detail took place in 2006 (Walsh *et al*., 2006) and because this stock is on a two year cycle for full assessment, attention will focused on monitoring annual changes in stock size and recent changes in stock size and temporal and spatial patterns of distribution since 2006 in relation to historical patterns.

Materials and Methods

Survey design

The stratification scheme is based on depth and shown in Fig. 1 (see Doubleday, 1981, for a review of procedures). The timing of the spring surveys, the frequency of fishing sets in the inshore strata (beginning in 1997) and the range of depths surveyed are shown in Table 1.

The 1984-2007 spring and the 1990-1994 fall surveys both covered depths from 45 to 731 m. Beginning in the fall of 1995 with the use of the new Campelen survey trawl, the coverage of the fall surveys extended to 1 500m. Due to mechanical problems with the CCG *Teleost* survey vessel, only sets in the deepwater strata of Div. 3L were fished in 1995 (Table 2). Surveys in 1999, and 2004-2007 had poor coverage in deep water strata (Table 2) (see Brodie and Stansbury, 2007) however, this is thought to have negligible effect on estimation of the relative abundance and biomass of yellowtail flounder, in most years, because the stock is found almost exclusively in depths less than 93 m. Nevertheless, the inclusion of these deepwater sets does lower the overall mean catch per tow by Division in those years. In the 2006 spring survey, there were also fewer sets in some strata in 3N, and stratum 373 was not surveyed. In recent years, this stratum contributed significant biomass to the total index and missing this stratum, and coupled with reduced coverage in other important strata, the 2006 estimates of abundance and biomass may not be comparable to estimates in other years. In addition, in years, 1995, 2002-2005, some northern portions of the surveys have overlapped into January of the following calendar year due to mechanical problems with the survey vessels. However, these delays are not expected to affect yellowtail flounder estimates because of its shallow water distribution in the southern section of the survey area.

Survey gears and vessels

From 1971 to 1982 the surveys of the Grand Bank were conducted by the 54 m side trawler, the FRV A. T. Cameron (ATC) using a two bridle Yankee 41.5 otter trawl rigged with rubber disk footgear. In 1983, this trawl was replaced by the three bridle Engel 145 Hi-Lift otter trawl rigged with large steel bobbin footgear and, at the same time, the A.T. Cameron was replaced by the 50 m stern trawler, the CCGS Wilfred Templeman (WT). Occasionally the W. Templeman's sister ship, the CCGS Alfred Needler (AN) took part in the surveys. In 1995, the old standard Engel trawl was replaced by a three bridle Campelen 1800 shrimp trawl rigged with 35 cm diameter rockhopper footgear. The Yankee and the Engel trawls were both towed at 3.5 kts, while the Campelen is towed at 3.0 kts (McCallum and Walsh, 1996). The Campelen trawl surveys of the Grand Bank began in the fall of 1995 aboard the CCGS Wilfred Templeman. The Campelen trawl also replaced the Yankee 41 shrimp trawl used in the annual fall juvenile groundfish surveys from 1985-94 (McCallum and Walsh, 1996). Beginning in the fall of 1996, the 63 m stern trawler, CCGS Teleost, began fishing mostly the deepwater survey sets of the annual fall surveys beyond 731 m in Div. 3LNO; however, shallower sets have also been fished when necessary (Table 2). In addition, the CCGS Alfred Needler has taken part in the fall surveys in 1996 and 2001. The Campelen trawl onboard the 2 other survey vessels is identical in construction and rigging as the one on the Wilfred Templeman. Since 1993, the geometry and performance of all bottom trawl surveys have been monitored by Scanmar trawl mounted acoustic instrumentation (Walsh and McCallum, 1995; McCallum and Walsh, 2001).

Time series

Conversion factors have been derived from comparative fishing trials to convert the 1984-95 spring and 1990-94 fall Engel trawl survey data into Campelen trawl units and were presented in Walsh *et al.* (1998a, 1998b). Survey data from 1971-82 time period has not been converted to Campelen trawl units and the unconverted time series can be found in the 1997 assessment paper (see Walsh *et al.*, 1997). Conversion factors into Campelen trawl units for yellowtail flounder have also been derived for the 1985-94 late summer-early fall juvenile groundfish series and the abundance and biomass data are found in a 2005 NAFO SCR paper (see Walsh, 2005). However, additional conversions of the database will be needed and consequently only annual spring and fall survey data from 1984 onward will be reported here.

Fishing and catch protocols

The Campelen carries out 15 minute tows using a towing speed of 3.0 kts and covers an average tow distance of 0.75 nautical miles. The catches are standardized to distance towed. The average wingspread used in estimating

swept area abundance indices is 16.84 m and the average swept area is estimated to be 24 950 m^2. After each set, all species in the catch are separated, counted and weighed. From each haul, the total catch or a sub-sample is taken to collect biological data on size, age, maturity and feeding for all commercial species.

Results

Spring Groundfish Surveys 1984-2007

Abundance and biomass trends:

Tables 4 to 9 give the survey catch rates by division in the form of stratified mean number and weight-per-tow by stratum. Tables 10-15 show abundance and biomass per stratum, along with confidence limits, for stock size in Div. 3L, 3N, and 3O, respectively, and table 28 gives combined estimates for Div. 3LNO from 1984-2007. Figure 2 show plots of the abundance and biomass estimates, as well as mean number and weight per tow, of surveys from 1984-2007. The high 1999 survey estimates point to a 'year effect' (Walsh *et al.*, 2000; STACFIS, 2000). Table 3 identifies large fishing sets that may contribute to variation seen around some of the estimates of stock size in a given year. Problems with the survey vessel in spring of 2006 resulted in reduced coverage, particularly in deep water of 3N and 3O. Only a few strata that were missed have had significant yellowtail catch in the past (notably strata 373) and it is felt that coverage of the area occupied by yellowtail flounder was sufficient to include estimates from this survey in the series.

In Div. 3L, there was a continuous decline in abundance and biomass from 1985 to "0.0 t" in 1995 (Tables 10, 13 and 28; Fig. 2). From 1996 to 1998, the stock showed a marginal increase to stabilize at an average biomass level of 500 t and then increased (by 5550%) to a level of 28 000 t in 1999 (Table 13; Fig. 2). From 2000-2002 the abundance and biomass declined dramatically and by 2002 the biomass was 600 t (1.6 million fish). From 2002-2006 the abundance and biomass have been variable but showed an overall increase to the highest estimates in the time series in 2006 at 251.5 million fish and 85.7 t biomass. In 2007, biomass and abundance estimates declined marginally, but remain second highest in the series. When the estimates are high most of the yellowtail flounder are generally found in stratum 363 and stratum 372.

In Div. 3N, in general, the majority of the stock was distributed in and around the Southeast Shoal area (strata 375, 376, 360 and 361 in Fig. 1), although in recent surveys, the abundance and biomass has been increasing in strata to the north of the Shoal, in particular strata 362 and 373 (Tables 11 and 14). The biomass index declined gradually from 168 000 t (435 million fish) in 1984 to 46 000 t (135 million fish) by 1994, a decline of 73% (Fig. 2). For the same period, the high abundance estimate of 478 million fish in 1989, was mainly due to the strong 1985 and 1986 year-classes which was not reflected in the biomass estimate for that survey. After a slight increase from 1994 to 1995, the survey biomass in 1996 jumped by 80% to 104 000 t (475 million fish) followed by a continued increase to a high of 238 000 t (965 million fish) in 1999 (Fig. 2). Since 1999, the survey abundance and biomass estimates have been variable, but increasing. The 2006 spring abundance and biomass estimates were the second highest and highest in the series, respectively (319 000 t; 1 billion fish), although stratum 373 was not surveyed in 2006, and fewer sets were conducted in several other strata, making it difficult to compare the index in 2006 to other years. In 2007 estimates remained high at 293 000 t and 954 million fish.

Variability around the 2001 estimate of abundance and biomass, both the highest estimates in their respective time series, was quite high (Fig. 2). Some recent estimates also have relatively wide confident limits. Some of this variation may be due to the several high catches. Over ½ of the estimate comes from sets in strata 360, 376, and 373. Similar to the 1999 survey where large catches were prevalent in strata 360, 361 362, 375 and 376, ten sets in 2001 had catches greater than 1 000 fish (5 in excess of 300 kg), in which one set caught 2400 (476 kg) in stratum 376 and another in stratum 373 caught 4800 (1.6 t) yellowtail flounder (Table 3). The biomass in stratum 373 contribute 79 000 t to the overall estimate of 298 000 t (Table 14). In 2003, there was also a few large catches (6> 900 fish; >200 kg) in strata 360, 373 and 376. In the 2000 and 2002 when the biomass was lower than in 1999, 2001 and 2003, there were a smaller number of incidences of large catches (2 and 4 >900 fish [>200 kg], respectively). In 2004 there were a few high catches in strata 360, 361 and 376 (4 >200 kg and >900 fish) and in 2005 strata 360, 361, 362, and 376 there were 4 sets greater than 200 kg. In 2006, 40% of the biomass estimate of 319 000 t is due to several sets in strata 360 that caught an average of 400kg and over 1300 fish per set. There is no one strata that dominates the estimate in 2007, however, and high catches are observed in several strata (360, 362, 373, 376; Table 3)

In Div. 3O, the abundance and biomass have shown a somewhat stable but slightly declining trend from 1984 to 1992 with an upward jump in 1993 before again declining (Tables 12 and 15; Fig. 2). The biomass index showed moderate fluctuations around an average value of 27 000 t (675 million fish) for the period 1984-92, increasing to 42 000 t (101 million fish) in 1993 and then declining to an average of 11 000 t during the 1994-95 period. The anomalous high estimate in 1993 may have been produced by the high catch rates in stratum 352 and is reflected in the high variability around the estimate. In 1996, the survey biomass dramatically increased by 492 % from 12 000 t (29 million fish) in 1995 to 71 000 t (162 million fish). Since 1996, estimates of biomass and abundance have been variable, but have shown an increasing trend and reach the series highs in 2006 (99 000 t) and 2007 (310 million fish) respectively. The discrepancy in trends between the two series is due to a shift in length frequency toward smaller fish in 2007 (Fig. 4). In this Division, most of the biomass is generally found in the two strata, 351 and 352 (see Fig.1 for location) which borders Div. 3N. In 2005, for example, 83% of the biomass estimate is due to catch in strata 351 and 352. Whether some of the annual fluctuations are related to movement between Div. 3N and 3O is unknown.

In the spring surveys of Div. 3LNO because the majority of the survey abundance and biomass was found in Div. 3N and then total stock trends mimic that of Div. 3N. From 1989-1998 there have been negligible amounts in Div. 3L until the 1999 survey (Tables 10, 13 and 28; Fig. 2) and in the most recent 2 years, there has been an increase of 340% in the biomass estimate compared to the first two years of the survey.

Biomass in Div. 3LNO increased rapidly in the late 1990s from the lowest levels in the mid-1990s (Table 28). Between 1999 and 2007, abundance and biomass estimates have been variable but have continued an upward trend (Fig. 2). The 2001 survey estimate of abundance and biomass was the most variable, and like the 1999 estimate it had many sets with large catches, including one with 1.6 t (4 824 fish) in Div. 3N. These large catches probably contributed to the high variability around the estimate. Thus it is unlikely that this is a year effect as was seen in 1999 since the 2001 biomass was very low in Div. 3L and even showed a small decline in Div. 3O.

In 2006, the biomass reached its highest estimate in the time series at 504 000 t (1.6 billion fish) (Table 28). The upward trend was seen in all three divisions, in particular Div. 3L where the highest estimate in the time series was seen. Similar to 1999 and 2005 surveys, more yellowtail were again caught in the northern area of Div. 3N and in the southern area of Div. 3L in 2005 and 2006 when compared to 2002 (see Brodie *et. al.*, 2003). The majority of the biomass was located in and around strata 351 and 352 of Div. 3O and in strata 360, 361, 375 and 376, the Southeast Shoal area in Div. 3N and large catches (>400 kg) were taken in strata 360, 362, 373 and 376 (Table 3). It is more probable to say that 2002 was a negative anomaly as reflected in the lack of fish in the northern areas.

Fall Groundfish Surveys, 1990-2007

Abundance and biomass trends:

Tables 16-20 show the survey catch rates in the form of stratified mean number and weight-per -tow by stratum and division for the fall surveys, 1990-2007. Tables 22-27 show abundance and biomass per stratum, along with confidence intervals for all divisions. Figure 3 shows plots of the abundance and biomass estimates, mean numbers and weights per tow by division from 1990-2007. Overall estimates by division and for 3LNO combined are given in Table 29.

In Div. 3L, abundance and biomass were very low and variable without trend from 1990-1995, reaching an estimate close to zero in 1994 (Fig. 3). Noteworthy is that a "0.0" t biomass was also estimated for the 1995 spring series. From 1990 to 95 the abundance varied around an average level of 2 million fish and then tripled to 6 million fish in 1995 and 1996. The biomass varied around an average level of 1 000 t from 1990-1997 before increasing to about 26 000 t in 2001 (Table 28). Similarly the abundance rose from 6 million fish in 1996 to 75 million fish in 2001. A drop in both the abundance and biomass indices (of 56% and 46% respectively) in 2002 was followed by a general increase to the series high in 2007 (28 000 t; 91 million fish). Estimates have wide confidence limits since 2001, and may be due in part to most of the biomass occurring in 2 strata (363 and 372, which border 3N, account for upwards of 90% of biomass estimates in some years). These increases in biomass in Div. 3L are thought to be the result of an extension of the range of yellowtail flounder with increasing stock size. There are obvious within year differences in the amount of yellowtail flounder caught in this Division and this is reflected in the high variability around the estimates for 1999-2001 and 2003-2007.

In Div. 3N, the stock size, from 1990-92, fluctuated around an average value of 47 000 t before doubling in size in 1993 to 94 000 t (Table 28). Since then the stock increased to 369 000 t in 2001 followed by a decrease to 252 000 t in 2003 (Table 28; Fig. 3). Values have fluctuated around 250 000 t since then, and in 2007 increased to the series high at 378 000 t. Similarly, the survey abundance from 1990-94 fluctuated around an average size of 222 million fish before showing a strong upward trend in 1995 to 509 million fish and reaching 1.3 billion fish in 2001, representing an overall increase of 160% (Table 28; Fig 3). From 2001 the abundance has decreased to a level of 900 million fish. The large jump in stock biomass seen in the 2003 spring survey was not evident in the fall survey (81% *vs.* 10%, respectively) because the fall 2002 survey did not show a decline as was seen in the spring 2002. From 2001-2006, both the abundance and biomass estimates have varied around a level of 1.0 billion fish and 270 000 t biomass, respectively (Fig. 3). In 2007, estimates increased once more to the highest in the series at 1.5 billion fish and 378 000 t.

Much of the large increases seen in the 2001 survey was attributed to large catches in stratum 376 ranging with 5 sets from 420 to 1150 kg (2 000 to 4 000 fish; 2 sets >800 kg) contributing 33%, to the divisional total estimate and to the large confidence interval around both estimates of abundance and biomass for 2001 (Table 3). In 2004 and 2005 several sets on the Southeast Shoal, (strata 375 and 376) were above 400 kg (1 515-4 473 fish). In 2006 large sets were taken in strata 360 and 376, and in 2007, 11 sets met the criteria for large sets (>900 fish or >400 kg). Similar to the spring surveys strata 360, 361, 362, 373 and 376 account for most of the biomass in this Division.

In Div. 3O, both the abundance and biomass index showed no obvious trend from 1990-96, with abundance fluctuating around an average value of 55 million fish and biomass fluctuating around an average level of 20 000 t (Tables 24 and 28: Fig. 7 and 8). Then in 1997, the biomass level jumped by 205% to 26 000 t (159 million fish). From 1997-99 the biomass showed a slight decreasing trend before turning upward to 98 000 t by 2003. Since 1997 the abundance has been somewhat variable but with an upward trend moving from 159 million fish in 1997 to 334 million fish in 2003. Both the 2001 and 2003 estimates of abundance and biomass were highly variable, but the 2003 estimates of biomass and abundance, which are the highest in the time series, are not as variable as 2001 (Tables 24 and 28). Although slightly lower than 2003, the abundance and biomass estimates in 2004 to 2007 has been stabilize but variable at an average level of 206 million and 64 000 t, respectively.

A large catch of 1200 fish (463 kg) in the western stratum, 338, may have contributed to the large variability around the 2001 fall estimate. Even though the estimate of stock size was low in 2002 there were 3 large catches taken on the Southeast shoal strata. In 2003-2007, there were a few large catches (>1 000 fish) (Table 3 above) taken in the surveys (weight range of 200-400 kg). Similar to the spring surveys, most of the biomass in this division was found in strata 351 and 352 which borders Div. 3N.

In the fall survey of Div. 3LNO, similar to the spring surveys, the majority of the stock was found in Div. 3N. The abundance and biomass in this division has shown a general upward trend since the start of the surveys (Table 29 and Fig. 3). Since 1993, when the survey biomass was estimated to be 113 000 t (372 million fish), there has been an increasing upward trend to a high of 476 000 t (1.2 billion fish) in 2001, representing a 321% increase in stock biomass. The 2001 survey biomass estimate of 476 000 t showed a 42% increase in size over the 2000 estimate. In recent years the biomass in the Southeast Shoal's strata, 375 and 376, contribute significantly to the overall biomass: 34 % in 2000 and 55% in 2001 and the large catches in these strata contribute to the high variability around these two survey estimates. Since 2001 the biomass has decreased to 368 000 t (1.3 billion fish) in 2003 putting the 2002 and 2003 more in line with the 2000 estimates. The annual up and down pattern in the biomass and abundance from 1998 to 2003 evident in the spring surveys is not apparent in the fall surveys (Tables 15 and 27). From 2002 to 2006, the abundance and biomass were stable around an average level of 1.3 billion fish and 369 000 t, respectively. In 2007, estimates were the highest in the series for 3LNO combined (482 000 t; 1.8 million fish).

Distribution

Yellowtail flounder is concentrated mainly in Div. 3N and the bordering areas of Div. 3O and to a lesser extent the border of Div. 3LN, similar to most years in the time series. Figures 5 to 8 show the standard number and weight from the catches of individual fishing sets from the spring and fall Campelen surveys for 2004-2007.

In the 2004-2007 surveys, yellowtail flounder were most abundant on the Southeast Shoal and the strata immediate to the west in Div. 3N (Fig. 5 to 8) most of which straddle the Canadian 200 mile (360 km) limit and extend into the

Regulatory Area. This confirms earlier descriptions of distribution (Walsh, 1992; Brodie *et al*., 1998; Walsh *et al*., 1999; 2000; 2001a, c; Simpson and Walsh, 2003; Walsh *et al*., 2004). Yellowtail flounder also appear to be more abundant in the Regulatory Area of Division 3N in the 1999-2005 surveys than in previous years and the northward distribution of the stock has extended to Div. 3L, similar to mid-1980s when the stock size was high (Simpson and Walsh 2003). Brodie *et al.* (1998) noted that the northward range extension of yellowtail flounder on the Grand Bank contracted with decreasing stock size during the mid to late 1980s and early 1990s so that the bulk of the stock was south of 45°N. Simpson and Walsh (2003) have shown that the observed range contraction of yellowtail flounder at low population levels represents selection for preferred habitats in the southern area of the Bank where depth and temperature are important covariates affecting the spatial pattern. Whereas during periods of large increases in stock size, the range of yellowtail flounder expands into less favourable habitats to north, depth but not temperature plays an influential role, and to a lesser extent westward in support of MacCall's Basin hypothesis. Recent tag returns from the 1998-2000 fishery have also confirmed the northward extension of the stock in recent years (Walsh *et al*., 2001b; Walsh *et al*., 2006).

Figure 9 shows a plot of the proportion of biomass north of 450 N from 1973 to 2007 and it is obvious that the range of the stock has extended northward since 1995. From 1996-2001, in 2003, and 2005-07, the proportion of biomass north of 450 N is higher in the spring than in the fall. The one obvious exception is the spring of 2002, when the proportion of biomass is much lower than in fall 2002, and is close to the low values in the early 1990s. The surrounding data suggest that the 2002 spring point is anomalous. The last 3 spring values are over 40%, and the last 3 fall values around 30%.

Colbourne and Walsh (2006) noted that in 1990-2005 surveys the centroid of the biomass of yellowtail flounder located within Div. 3NO was found over the Southeast Shoal of the Grand Bank. This area corresponds to some of the warmest bottom temperatures found anywhere on the Grand Banks. The authors reported that spring bottom temperatures in this region range from a minimum of 1-2°C during cold years (1990) to 3-4°C during warm years (1998 and 1999). Fall bottom temperatures are in general warmer than spring values ranging from 2-3^{o}C in most years to maximum values of between 7-8°C during extreme years (1999). Since 1999, with the exception of 2002, survey catch rates of yellowtail have remained significantly higher than those before 1995. With the exception of 2003 spring bottom temperatures have also been higher than they were in the early 1990s. The cold temperature values observed in the spring of 2003 were anomalous and lasted from April to June and were above average during the remainder of the year (Colbourne *et al*., 2004). However there is no indication that the temperature had a limiting factor in the northward distribution of yellowtail flounder in the 2002 spring survey (See Fig. 12); and 2004 fall survey (Fig. 12 and 13; Colbourne and Walsh, 2006). Temperature correlations have not been examined for the 2006 and 2007 survey data.

In summary, there was a steady increase in the abundance of yellowtail flounder coinciding with a northward expansion of the stock from 1995 up to 2007 that also coincided with an increasing trend in bottom temperatures (until 2006, at least). Colbourne and Walsh (2006) noted that these results indicate a temperature preference for yellowtail towards the warm water habitat of the Grand Banks. The 2004-2005 surveys showed increasing frequency of catches in the northern areas, especially Div. 3L in the spring (which continued in 2006 and 2007) with some catches being taken in less than 0°C in the fall of 2004. Temperature data has not been examined for the 2006 and 2007 Survey data in relation to yellowtail distribution. Vessel problems resulted in reduced coverage in the 2006 spring survey and estimates from that survey may not be comparable to those in other years.
