**Abstract**

The Norwegian shrimp survey in Skagerrak and the Norwegian Deep (ICES Divs. IIIa and IVa east) has gone through large changes in recent years. The result is a series of four different surveys, lasting from one to nineteen years. New series were initiated in both 2004 (May) and 2006 (February). Conducting the survey in the 1<sup>st</sup> quarter gives good estimates of recruitment and SSB. Thus, a new time series at the most optimal time of year is established.

There was no trend in the annual survey biomass estimates from the mid 1990s to 2002 when this series was discontinued. The 2004 and 2005 mean values of a new biomass index series were not statistically different. The 2007 index was 77% higher than the 2006 value. In 2008 the biomass index decreased back to the 2006 level. The decline continued in 2009 and 2010.

Recruitment (abundance of 1-group) in Skagerrak was much lower in 2008-2010 than in the two preceding years, implying low catches in 2011. In 2006-2009 recruitment was much lower in the Norwegian Deep compared with Skagerrak. However, in 2010 the 1-group is of equal size in the two areas. The steadily decreasing recruitment in 2008-2010 is probably the main reason behind the decreasing stock size. The SSB-index shows a decreasing trend since 2007.

The index of shrimp predator biomass was estimated to 49.23 kg/nm in 2010. A predator index excluding saithe and roundnose grenadier shows less interannual variation.

**Introduction**

A trawl survey for northern shrimp in Skagerrak and the Norwegian Deep (ICES Divs. IIIa and IVa east, and the far north-east corner of Div. IVb) has since 1984 been conducted annually by the Norwegian Institute of Marine Research with the objective of assessing the biomass, recruitment, and demographic composition of the shrimp stock and the size of the stocks of shrimp predators, as well as measuring hydrographical conditions in the distributional area of shrimp.

The survey data consist of: 1) one time series based on a survey conducted in October/November 1984-2002 using R/V *Michael Sars* and the Campelen-trawl; 2) a point estimate for 2003 as R/V *Michael Sars* was taken out of service and substituted with R/V *Håkon Mosby*, whose winches at that time were not powerful enough for the Campelen-trawl, resulting in the survey being conducted with the Shrimp trawl 1420; 3) a start of a potential new series as the survey in both 2004 and 2005 was conducted in May/June with R/V *Håkon Mosby* using the standard Campelen trawl; and 4) a start of yet a new series in February 2006 still using R/V *Håkon Mosby* and the Campelen trawl. Conducting the survey in the 1<sup>st</sup> quarter gives good estimates of the 1-group (recruitment)

and SSB (berried females) and was strongly recommended by the *Pandalus* working group in 2004 (ICES 2005). Since 2006 the survey has been conducted in January/February. Thus, a new time series at the most optimal time of year is established.

This paper presents the results of the 2010 survey.

## Material and Methods

### *Survey design*

The design of the new time series (2004-2005 and 2006- recent) is similar to the old one (1984-2002) (ICES 2005).

The survey area covers depths of approximately 100 to 550 m in ICES Divs. IIIa and IVa east. A couple of stations are also located in the far north-east corner of Div. IVb. The survey is stratified by four depth zones (100-200 m, 200-300 m, 300-500 m, and >500 m), and area (Table 1, Fig. 1). In 2007 the strata division was revised. The depth contours were updated using GIS and the bathymetric database GEBCO, and the strata areas were recalculated accordingly. The strata 1-4 were extended north to 60° N in order to incorporate the two northernmost stations in the strata system, and the deep water area in the middle of Skagerrak (>500 m) was included as a 17<sup>th</sup> stratum as four trawl stations are located in this area. A second revision of the strata system in 2008 moved the northern border of stratum 1 to 59° N as the two southern trawl stations in this stratum cannot be considered representative of the whole area north to 60° N (Fig. 1). Furthermore, the strata areas were recalculated using an “equal area” projection which gives more correct area estimates than the earlier used projection. The survey area is now estimated to cover 15 749 nm<sup>2</sup> (Table 1).

The survey has a fixed station design, assuming that the temporal variation in the shrimp stock generates the necessary randomness. In 2006 it was decided that the 100 stations trawled during the 2000 survey should be considered fixed stations for future surveys. In 2008 thirteen stations (positions found in old survey reports from 1984-1996) were added in order to obtain a better coverage of the area (Fig. 1), and two old stations were deleted from the list, resulting in a new total of 111 trawl stations. The deepest and shallowest stations have depths of respectively 540 and 111 m. Ideally, all stations should be trawled every year, giving a coverage of one haul per 142 nm<sup>2</sup>. However, this rarely happens due to time and weather constraints.

In 2010 the survey was carried out from January 14 to 31. The trawl used is a Campelen 1800/35 bottom trawl with rockhopper gear. In 2006 the rigging was changed with more float added in order to reduce the number of “mud hauls”. This worked out very well, and the new rigging has since been kept. Mesh size in the cod end is 22 mm with a 6 mm lining net. Tow duration was 1 hour until 1989 when it was reduced to 0.5 hour. When towing on fish banks the tow duration is reduced to 5-10 minutes to prevent the trawl filling up with fish. Tow speed is roughly 3 knots. In 2010 the average tow speed was 2.85 knots (SD = 0.20). No compensation for diurnal vertical migration is made. Strapping was introduced on the survey in 2008 in order to ensure a fixed trawl geometry. Due to poor door spread on the 2009 survey, various rope lengths and distances between the rope and the doors were tried out. A 10 m rope 200 m in front of the doors gave an optimal door spread of 46-47 m. This rigging was kept on the 2010 survey.

### *Stock size index*

The swept area was estimated by applying a wingspread of 11.7 m to tow length. Tow length was time towed multiplied by an average towing speed of 3 knots. The swept area is thus 0.019 nm<sup>2</sup>/hour.

The catch in each tow divided by the swept area represents a sample of shrimp density in a stratum. From these samples the mean and standard error of the density in each stratum was calculated and multiplied by the area of the stratum to give estimates of stratum biomass and abundance. The biomass and abundance for the 17 strata were summed to give the overall values for the survey area. Standard errors were corrected in 2009: SE (whole survey area) =  $\sqrt{[\sum (SE (\text{stratum})^2)]}$ .

A biomass index of shrimp predators was calculated as average catch/nm over all hauls of 22 fish species.

### *Biological samples*

Samples of 250-300 shrimps are taken from each trawl haul, sorted by sexual characteristics, and measured to the nearest mm below (carapace length (CL)). Overall length frequency distribution, as well as distributions per area (Skagerrak and the Norwegian Deep), were estimated. The length frequency distributions were partitioned into age groups by modal analysis using the method of Bhattacharya (1967) (software: FISAT).

A recruitment index was estimated as the numbers of 1-year old shrimp from the modal analysis. There is a good correlation between the number of 1-year old shrimps in January/February in one year and the number of 2-year old shrimps the following year, despite few data points (Fig. 2).

A SSB-index was estimated as the total numbers of berried females, females with head roe and recently spawned females. Berried females are dominating the catches in January-February.

### *Hydrographical measurements*

In all present and past surveys CTD casts have been made at each station, but previously the data were not analysed. To avoid damages on the equipment, the CTD is not lowered further than 10 m above the bottom. Previous missing 2006-data was added to Table 2.

## **Results**

### *Area coverage*

Two days out of the 18 days of the 2010 survey was reserved for hydrographical investigations. 98 out of the 111 fixed stations were covered (Fig. 3). Out of these three tows were invalid ("mud hauls"). These data were not used in the calculations.

### *Temperature and salinity*

The average temperature (10 m above the bottom) in January/February in the survey area has lied between 7 and 8 °C the last five years. In 2006-2009 the bottom temperature was slightly higher in the Norwegian Deep compared with Skagerrak, while in 2010 the pattern was opposite (Table 2, Fig. 4). Average salinity has varied between 34.9 and 35.3 ‰ in the same time period.

### *Strapping*

Strapping has caused the average door spread to decrease from 52.9 m (SD: 4.4) and 51.6 m (SD: 1.8) in 2006 and 2007 to 47.0 m (SD: 1.7) in 2008, 45.3 m (SD: 3.2) in 2009, and 46.9 m (SD: 2.2) in 2010. The former relationship of increased door spread with increased depth is not seen in the 2008 and 2010 tows (Fig. 5). In 2009 there was a slight decrease in door spread with depth, probably due to difficulties with door spread at this year's survey. The difference in door spread between the different years is not corrected for.

### *Biomass indices*

The biomass index increased from the late 1980s to the early 1990s, remained at a stable level until the mid 1990s where after it started fluctuating at a slightly higher level (Table 3, Fig. 6). This series was discontinued in 2002. The very low 2003 biomass index could have resulted from the use of the Shrimp trawl 1420, which has mesh size in the cod end of 36 mm, and no lining. However, the trawl opening is taller compared with the Campelen trawl. The 2005 mean value is lower than that of 2004, but not statistically different. The 2007 index was 77% higher than the 2006 value, but was heavily influenced by the very high mean biomass in stratum 16 (Table 3), which was due to the high biomass of one particular trawl station. In 2008 the biomass index declined to the 2006 level, and the decline continued in 2009 and 2010 (Figs. 6 and 7).

As the time series is short (only 5 years), there are few years with which to compare the low value of 2010, and it is not possible to state whether the 2010-index is extraordinarily low. However, since the LPUE-index has been decreasing since 2007 and the 2009- landings were the lowest since the mid-1980's and the 2010-landings (first six months) are even lower (Søvik and Thangstad 2010), there are reasons to believe that the shrimp biomass in 2010 is at a very low level.

In 2006-2009 the estimated shrimp biomass was higher in Skagerrak (Div. IIIa) compared with the Norwegian Deep (Div. IVa east), however, in 2010 this pattern was reversed with a slightly higher estimated biomass index in the Norwegian Deep (5 840 t) compared with Skagerrak (4 290 t).

#### *Size, age and sex distribution*

There seems to be only three age groups in Skagerrak, but four in the Norwegian Deep (Table 4). The total length distribution resembles the distribution in Skagerrak due to the larger catches in this area (Fig. 8).

In Skagerrak, the size distribution of the 2006 survey showed a large mode of 1-year old shrimp (recruitment) (Fig. 8b), which appeared as a very large mode of 2-year old shrimp dominating the catches in the 2007 survey. The 1-group in 2007 was of equal size as the 1-group in 2006, however, the 2-group in 2008 was much smaller than in 2007. The 1-group in 2008 was much smaller than in the two previous years (Figs. 8b, 9), and appeared as a comparatively small 2-group in 2009. The 1-group declined further in 2009 and 2010.

In the Norwegian Deep in 2006-2009, the 1-group was very small compared with Skagerrak (Fig. 8, 9). The inter-area difference was, however, less pronounced in 2008-2009 compared with 2006-2007, due to a sharp decline in recruitment in Skagerrak. In 2010 the 1-group is of equal size in the two areas.

The much larger abundance of 1-year old shrimp in Skagerrak indicates that these waters constitute a nursery area for the stock. The steadily decreasing recruitment in 2008-2010 is probably the main reason behind the decreasing stock size. However, it is not known why recruitment is decreasing. The small 1- and 2-groups in 2010 imply low catches also in 2011.

SSB had decreased since 2007 (Fig 10a). So far no relationship is found between SSB and recruitment (1-year old shrimp), but this can also be explained by few data points (Fig. 10b).

#### *Predator abundance*

Mean catch per trawl haul (kg/nm) in 2010 are given for various shrimp predators (Table 5). Saithe is the most numerous species, with an average catch of 18.53 kg/nm. The total index of shrimp predator biomass was estimated to 49.23 kg/nm in 2010, which is below the mean of the series for 2006-2010 (Table 5). Results from the first survey series (1984-2002) range from 28.6 to 63.1 kg/nm (ICES 2004), while in 2004-2005 the indices were respectively 58.1 and 115.4 kg/nm (ICES 2006).

The index of predator biomass is heavily influenced by the indices for saithe and roundnose grenadier. Some shallow trawl stations yield large catches of saithe, while roundnose grenadier is caught mainly in the deep parts of Skagerrak. Thus the value of these two indices, and consequently the total predator index, depends largely on the number of shallow and deep stations covered each year. A predator index excluding saithe and roundnose grenadier shows less inter annual variation (Table 5).

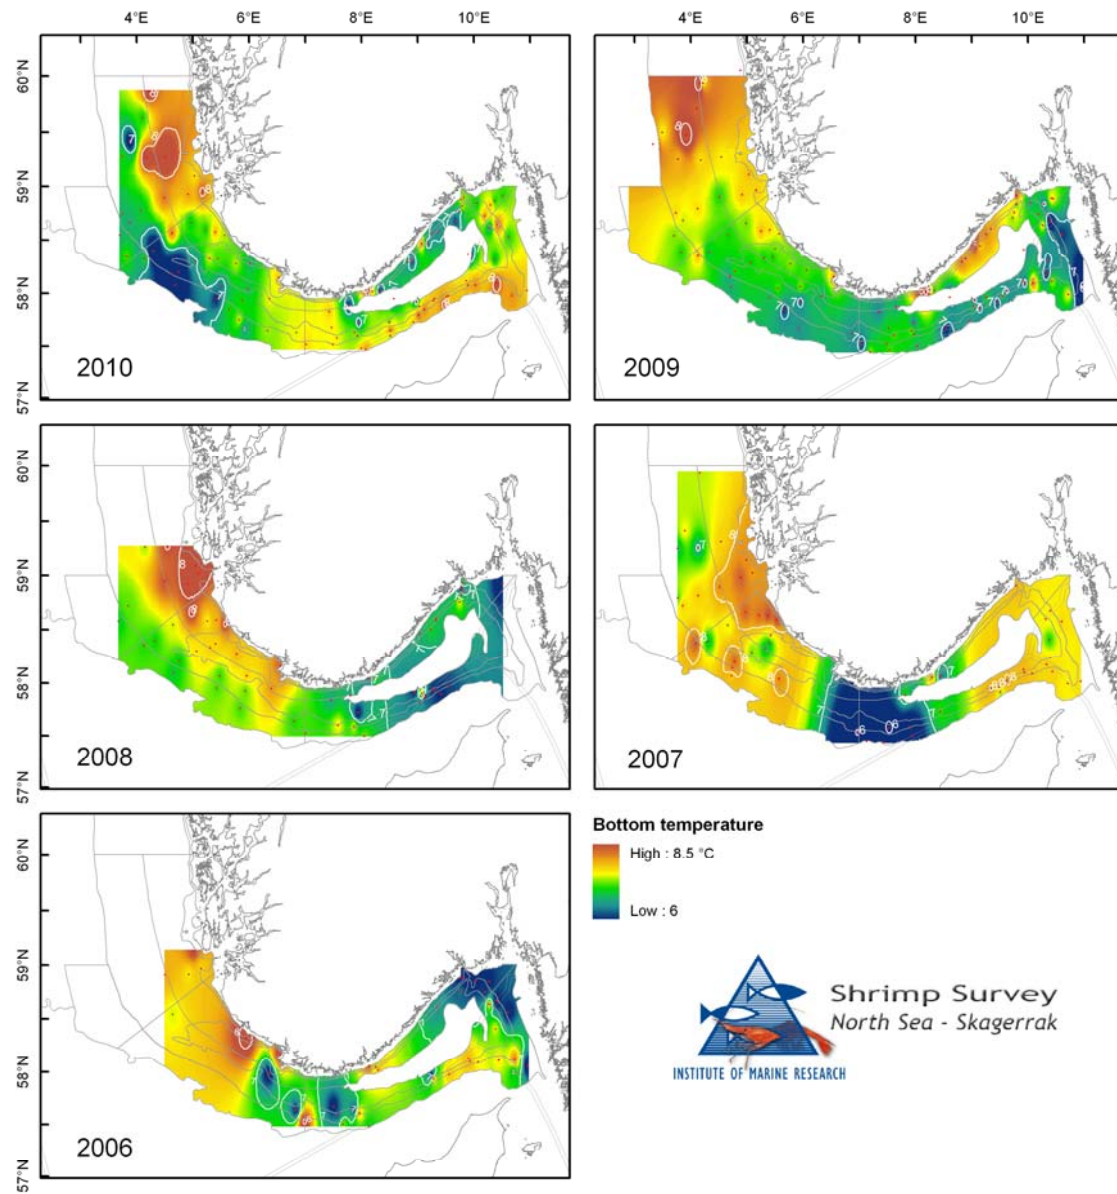

**Fig. 1.** Norwegian shrimp survey in Skagerrak and the Norwegian Deep (ICES Divs. IIIa and IVa east): the revised strata system (introduced in 2007 and adjusted in 2008) with the 111 fixed trawl stations. Trawl stations marked in red were introduced in 2008 (see text). Strata areas are given in Table 1.

**Fig. 2.** Correlation between the index of 1-year old shrimps (abundance in millions) in January/February, year  $t$  and the index of 2-year old shrimps (abundance in millions) in January/February, year  $t+1$ , in Skagerrak and the Norwegian Deep (ICES Divs. IIIa and IVa east). Data from 2006-2010.

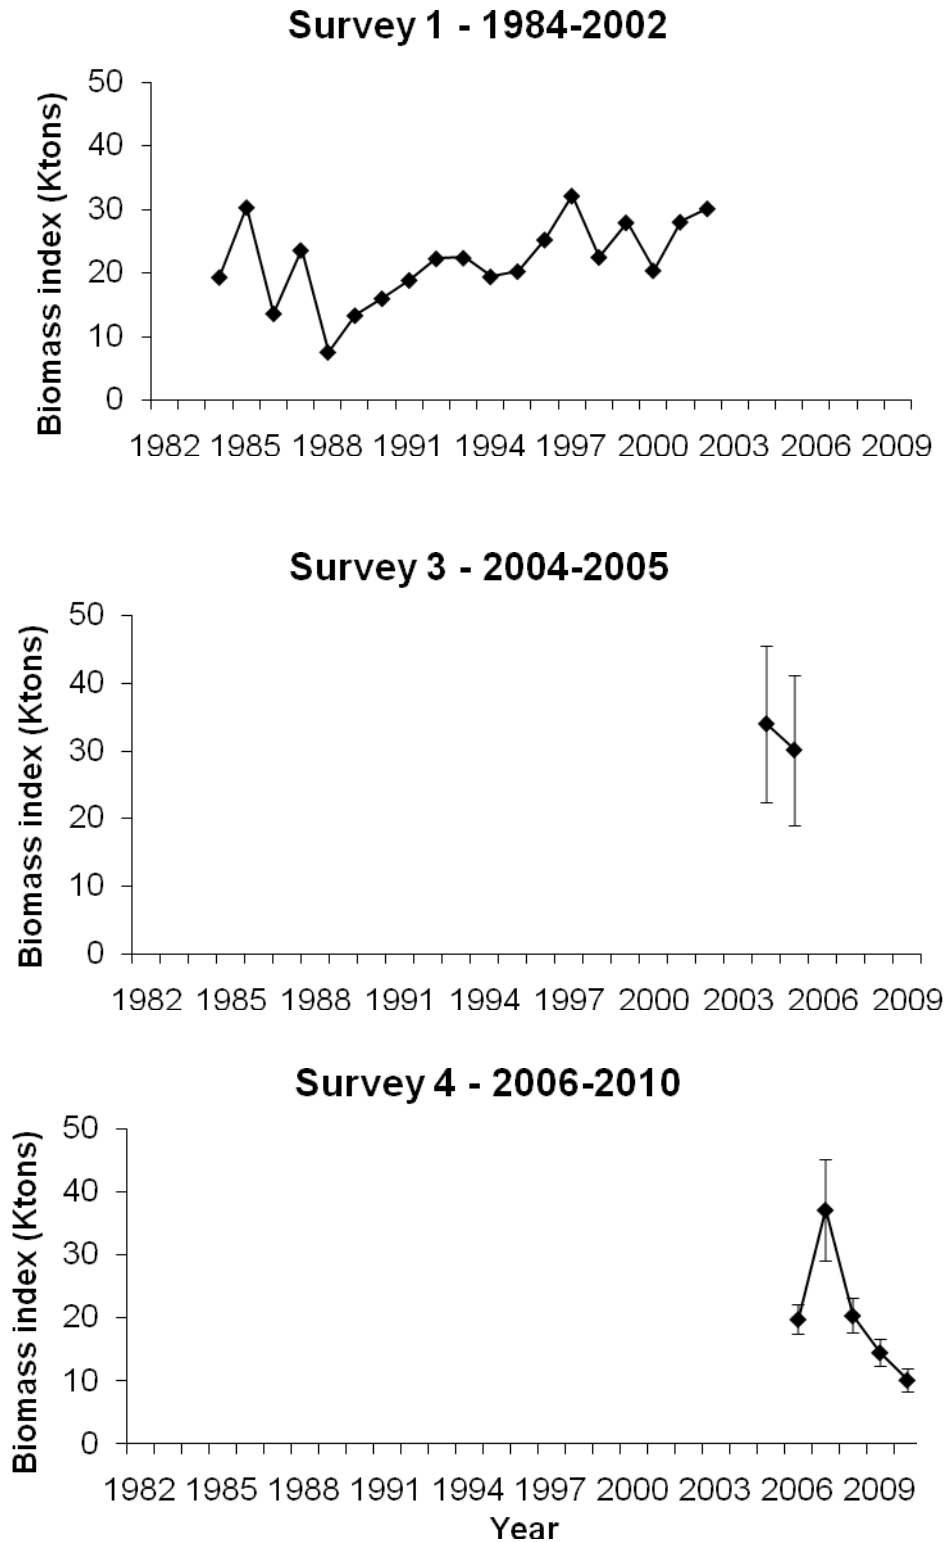

**Fig. 3.** The Norwegian shrimp survey in Skagerrak and the Norwegian Deep (ICES Divs. IIIa and IVa east) in January 2010 with R/V *Håkon Mosby*: sailing route and trawled stations.

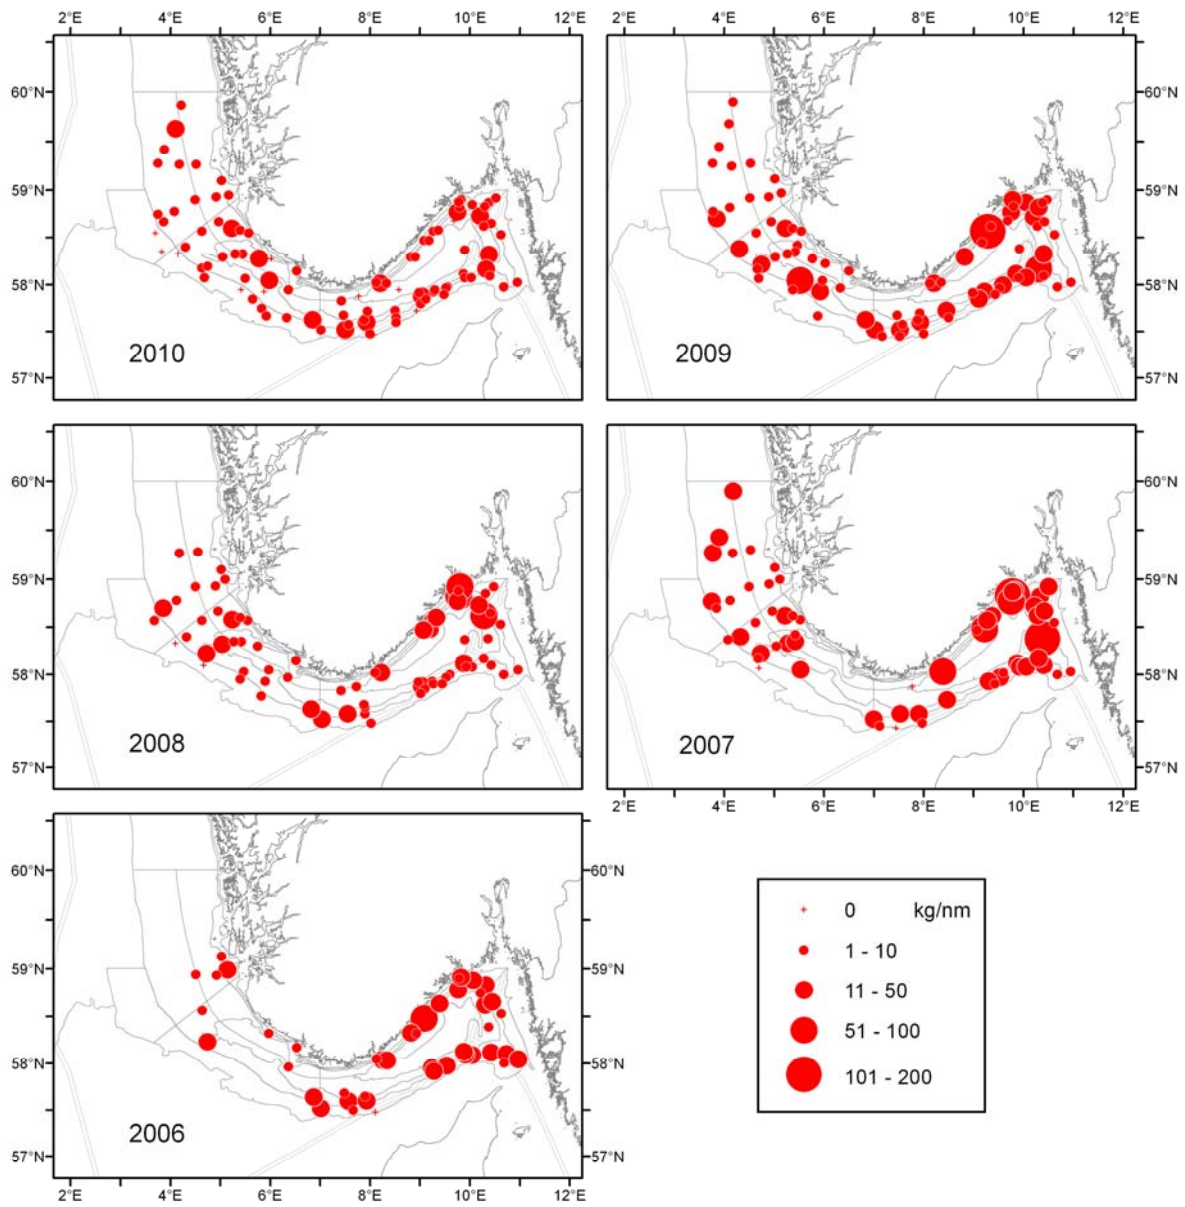

**Fig. 4.** Temperatures (°C) measured with CTD on trawl stations during the 2006-2010 shrimp surveys in Skagerrak and the Norwegian Deep (ICES Divs. IIIa and IVa east).

**Fig. 5.** Door spread vs. depth on the shrimp survey in Skagerrak and the Norwegian Deep (ICES Divs. IIIa and IVa east) in 2006-2010. Strapping was used in 2008-2010, but not in 2006 and 2007.

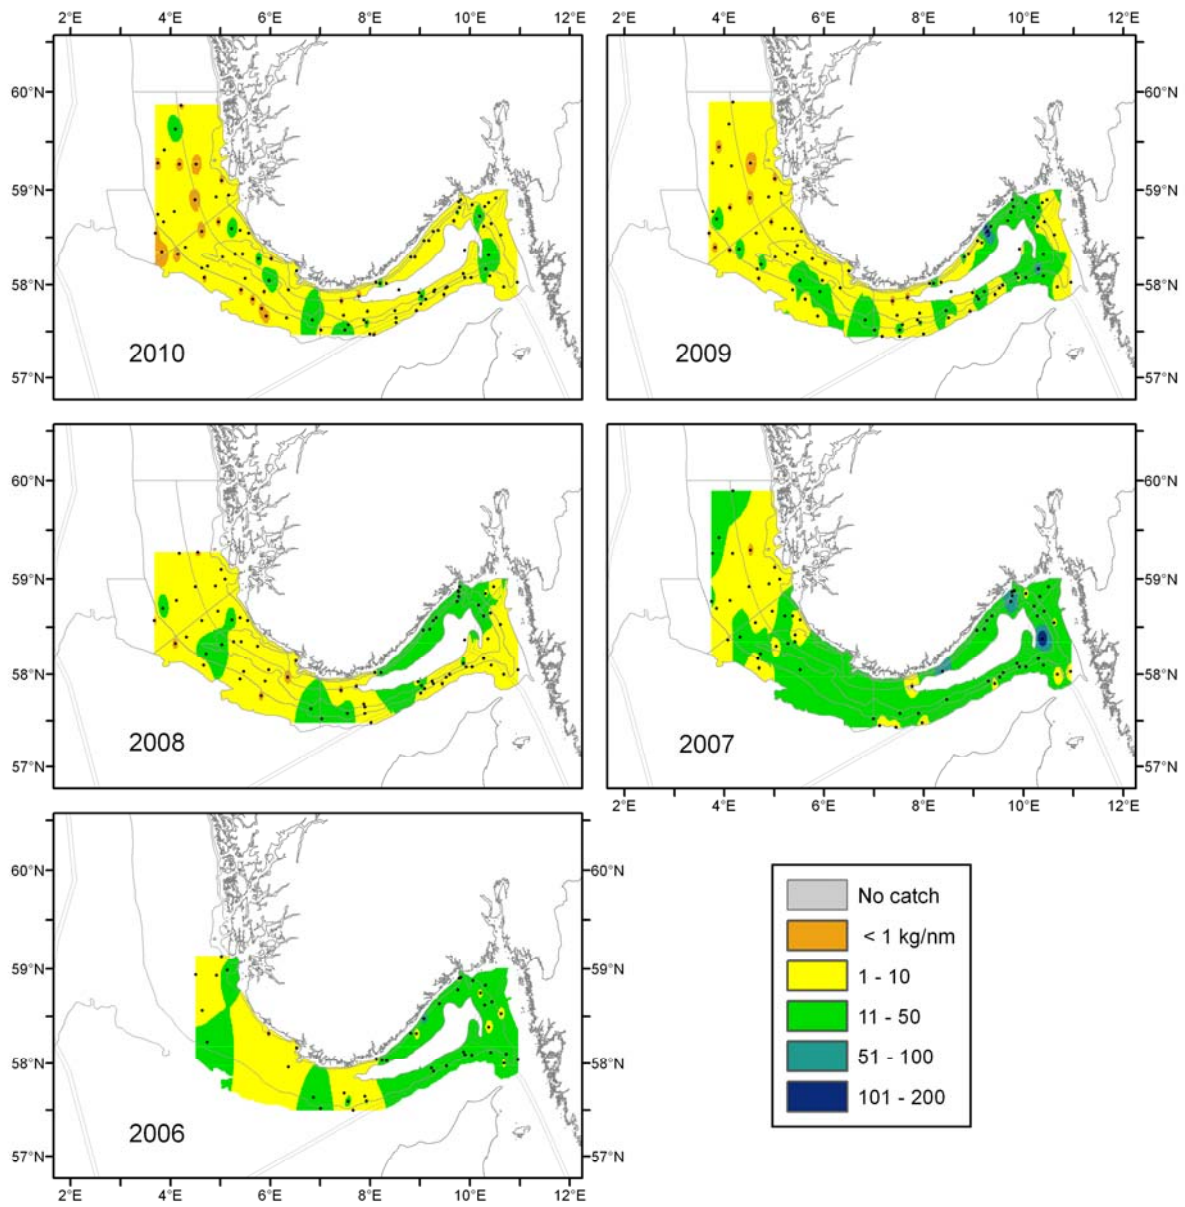

**Fig. 6.** Estimated survey biomass indices of shrimp (*Pandalus borealis*) in Skagerrak and the Norwegian Deep (ICES Divs. IIIa and IVa east), 1984-2010 (see Table 3). The 2003-estimate is not shown. Standard errors have been calculated for the 2004-2010 surveys.

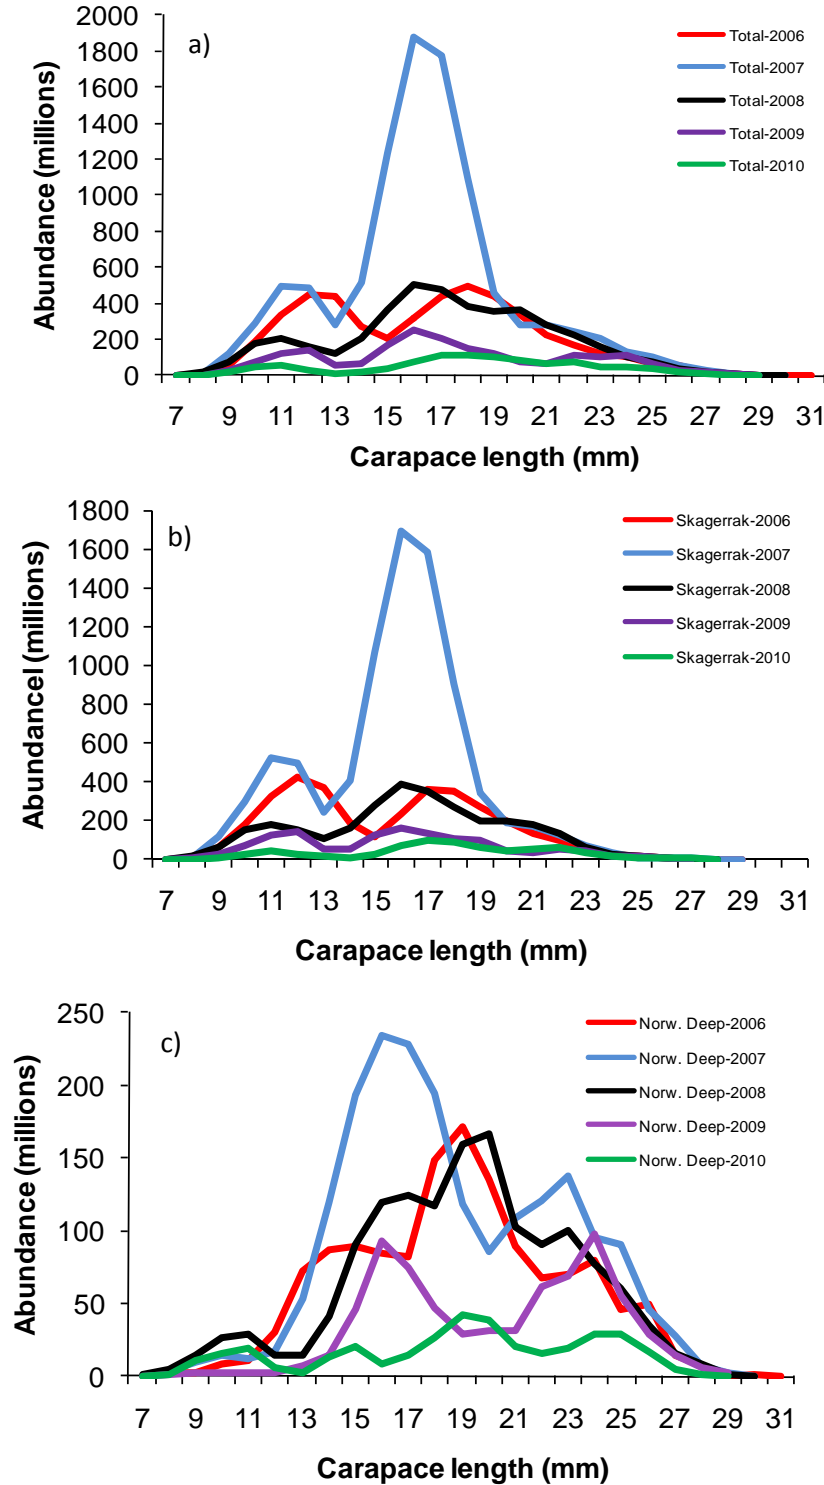

**Fig. 7a.** Shrimp catches per trawl station (kg/nm) from the Norwegian shrimp survey in Skagerrak and the Norwegian Deep (ICES Divs. IIIa and IVa east) in January/February 2006-2010.

**Fig. 7b.** The distribution of shrimp (kg/nm) from the Norwegian shrimp survey in Skagerrak and the Norwegian Deep (ICES Divs. IIIa and IVa east) in January/February 2006-2010.

**Fig. 8.** Length frequency distributions for a) the overall area, b) Skagerrak (ICES Div. IIIa), and c) the Norwegian Deep (ICES Div. IVa east). Data from the Norwegian shrimp survey 2006- 2010. Note different scales on y-axes.

**Fig. 9.** Recruitment index (abundance in millions) of 1-year old shrimp in Skagerrak (ICES Div. IIIa), the Norwegian Deep (ICES Div. IVa east), and in the overall area for 2006-2010.

**Fig. 10.** a) SSB index (abundance in millions) in 2006-2010, and b) SSB-recruitment relationship 2006-2009 in Skagerrak and the Norwegian Deep (ICES Divs. IIIa and IVa east).
