SCIENTIFIC COUNCIL MEETING – JUNE 2012

Performance and description of Canadian multi-species surveys in
NAFO subarea 2 + Divisions 3KLMNO, with emphasis on 2009-2011.

Abstract

We update basic survey performance statistics and document the spatial coverage of the annual spring and autumn multi-species surveys conducted by the Department of Fisheries and Oceans, Newfoundland Region over 2009-2011. Noteworthy issues include modifications to survey density, some prioritizing of survey efforts, and coverage shortfalls during fall surveys. The impact of these items in relation to the stock assessments of various species is briefly discussed.

Introduction

The Canadian Department of Fisheries and Oceans, Newfoundland Region, has undertaken stratified random surveys in portions of NAFO subareas 2 +3 since the early 1970's. A full description of the history of these surveys, survey stratification, trawl gear, towing protocols, vessels employed, as well as details of spatial coverage up to the surveys of 2008 are detailed in documents by Healey and Brodie (2009), Brodie and Stansbury (2007) , Brodie (2005), and references therein.

These surveys are stratified by depth range, and stratification maps of Divs. 2GHJ3KLMNO are illustrated in Figs. 1-8. Survey "sets" (a sample taken at a randomly selected sampling unit) for this random-stratified survey are distributed using a proportional-allocation scheme, whereby the number of sets allocated for a given stratum is proportional to the stratum area, subject to the condition that each stratum must be allocated a minimum of two sets. Tow sites are randomly selected from sampling units within each stratum, with each sampling unit typically encompassing an area of approximately 3.5 square nautical miles (Doubleday (ed.) 1981). Within each stratum, one alternate station is also selected, and is occupied if a sample from one of the other units cannot be obtained (e.g. untrawlable bottom). When computing the stratified estimators of abundance or biomass for any given species, individual strata must have a minimum of two successful survey sets to be considered completed.

The Canadian Coast Guard vessels employed during current fall surveys are the CCGS *Alfred Needler* and the CCGS *Teleost*. The CCGS *Alfred Needler* (overall length 50m) conducts fishing sets at depths of 732m or less, whereas the CCGS *Teleost* (overall length 63m) completes survey sets to depths of 1500m. During spring surveys, typically only the CCGS *Alfred Needler* is used; the CCGS *Teleost* has been deployed at times when the CCGS *Alfred Needler* was unavailable due to significant mechanical problems. The CCGS *Wilfred Templeman*, which had been one of the primary vessels for survey work in the Newfoundland Region, has recently been decommissioned.

Focus herein is upon the performance of the spring and fall surveys in 2009-2011, with additional attention given to some revisions of fall survey efforts since the mid-2000's.

Methods

Survey results were analyzed to determine the total number of successful fishing “sets”, sampling events for which all tow protocols are met, and with minimal or no damage to the survey gear. Counts of successful sets for both spring and fall surveys were organized by stratum, division and vessel. Survey start and end dates and the depth ranges covered in each of 2009-2011 were also tabulated. For comparative purposes, we include similar information over the entire period in which the Campelen 1800 shrimp trawl has been used. This sampling gear was first deployed in the 1995 fall survey, and has been used in all spring surveys since 1996. McCallum and Walsh (1996) provide a detailed description of the Campelen 1800 trawl.

In addition to the number of sets completed, tabulations of the number of sets allocated per division and survey were compiled to demonstrate slight changes to the intensity of the fall survey in recent years, and to also provide a comparison with the number of sets realized.

Fall Surveys

Division 2G has not been surveyed since 1999 and is excluded from the present survey design. Since the early-2000s, coverage of Division 2H was planned for every second year, though the amount of available vessel time was unchanged across years. Divisions 2J3KLMNO are covered annually, and the entire survey is generally conducted from early-October to mid-December.

The overall density of the Canadian fall survey was altered slightly prior to the beginning of the 2008 survey (Healey and Brodie, 2009). The number of sets allocated for the fall 2008 survey was decreased by approximately 7.5% from 800 to 741 compared to the allocation throughout Divs. 2HJ3KLMNO in prior years. The reduction was implemented for two reasons. First, continual mechanical problems with research vessels in recent years lead to a significant reduction in the realized number of sampling sets compared to the total number of sets allocated (Table

1). Secondly, a program of expanded sampling of numerous “non-commercial” species to gain a broader perspective on ecosystem dynamics and trends in support of an Ecosystem Research Initiative (ERI) was initiated during 2008.

For the fall 2009 survey, the total number of sets allocated was maintained at 741. Div. 2H was not scheduled to be sampled during 2009 as per the biennial sampling design and it was excluded during this year, resulting in an overall per-capita increase in the number of sets planned for remaining divisions, to levels even higher than when 800 total sets were allocated.

During the fall 2010 survey, allocations for Divisions 2J3KLNO were restored to the levels of 2007 and prior years. The allocation for Div. 2H was slightly less than intended for that year and was inadvertently maintained at the 2008 level – the most recent year in which 2H had been covered and Div. 3M was excluded from the survey design entirely. In total, 768 sets were allocated for completion.

The survey allocation for the fall of 2011 included coverage of Div. 2H (84 planned sets) – and current plans are to continue surveying Div. 2H annually. To facilitate this, both the inshore strata of Divs. 3K and 3L (19+34 planned sets) and the deep-water (>732m) strata of Divs. 3NO (48 planned sets) were excluded from the survey design when planning the fall 2011 survey, yielding a reduction of 101 planned sets compared to the 2010 allocation. (The inshore strata were added to the survey design in the mid-1990s.) Portions of the deep-water strata in Divs. 3NO area are unsuitable for trawling and typically, a considerable amount of time in previous years was used to search for deployment sites near the intended site. There was a slight reduction in the number of vessel time available in 2011 but no further reductions to the planned coverage were considered necessary to take this into account.

A further significant change to the planned coverage occurred midway through the 2011 survey to compensate for lost survey time, mainly because of mechanical problems with one of the research vessels. In the time remaining it would not have been possible to fully cover the remaining planned areas. Therefore, a decision was made to reduce the survey allocations across Divs. 2J, 3K and 3L, to permit coverage of strata that are important to a number of resource assessments. These reductions resulted in the exclusion of 14, 29 and 23 planned stations, respectively. In addition, it was also decided to drop the deep water strata of Div. 3L (30 sets originally allocated) from the 2011 survey. Overall, the initial planned coverage of 674 sets was reduced to 578 planned sets after these mid-survey adjustments.

Spring Surveys

Spring survey allocations have been consistent during recent years. A total of 334 sets are allocated annually, which includes 34 sets within the inshore strata of Div. 3L. During the spring surveys, these sets are considered of lower priority and are infrequently occupied. The spring survey encompasses Divs. 3LNOPs, and is typically conducted from early-April through to late June. Though the spring survey covers Divs. 3LNOPs, we report on performance within Divs. 3LNO only.

Results and Discussion

A synopsis of the successful sets during fall surveys over 1995-2011 (Table 2; see also Fig. 9a) indicates that challenges in completing fall surveys have continued over 2009-2011. Although the set counts and completion rate were much improved in 2010, there were significant shortfalls in both 2009 and 2011. The total number of completed sets in 2009 and 2011 were among the lowest for the Campelen time-series – only the surveys of 1995 and 2008 had less sets realized. Divisionally, the greatest impact in both years was with Divs. 2J3KL, particularly so in 2011. Just 340 sets were completed in Divs. 2J3KL in 2011, the second lowest in the time-series.

Detailed examination of coverage in the 2009-2011 fall surveys (Table 3) identifies where some of the gaps exist. In 2009, the inshore strata in Divs. 3KL (Div 3L: strata 784-800; Div. 3K: strata 608-616) and eight deep-water strata in Div. 3N were not completed. Only partial coverage of the inshore strata was attained during 2010. In addition, the deep-water portions of Divs. 3NO were not covered, plus six strata were not fully completed (2H-937, 2H-948, 2H-949, 2H-950, 3N-378 and 3N-725). The deficiencies of the 2011 survey include no coverage in the deep-water of Divs. 3NO or the inshore strata in Divs. 3KL, five incomplete strata in Div. 2H (936, 937, 948, 949, and 950), with reduced set counts across most of Divs. 2J3KL due to the mid-survey adjustments noted previously. Comparison of intended versus realized sets (Fig. 9b) indicate completion rates of 79%, 91%, and 84%, respectively during 2009 to 2011.

In contrast to fall survey extensions into January during the mid-2000s, surveys of 2009-2011 were conducted within the normal timeframe. One anomaly was that during the fall of 2010, the survey within Div. 3O was a couple of weeks later than normal.

In the spring surveys of 2009-2011, the number of sets completed (Table 4; see also Fig. 10a) are quite good – the percentage of intended sets completed over 1996-2011 has averaged 96%. Although the 2010 survey had the third lowest set count for this time-series, only twelve fewer sets than the total allocation were completed. With the exception of the 2006 survey, spring surveys have generally been fully completed (Fig. 10b). The completion rate of the spring surveys of the past three years are 100%, 96%, and 99%, respectively. Mechanical difficulties with the CCGS *Alfred Needler* in 2009 required the utilization of the CCGS *Teleost*, which completed 81 of the 299 successful sets over Divs. 3LNO.

Set counts by stratum for spring surveys in 2009-2011 (Table 5) show that the only coverage issues were two incomplete strata within Div. 3L during 2010 (strata 343 and 729), and two incomplete strata during 2011 (3L-732 and 3O-720). The timing of the recent spring surveys was within the typical range.

In addition to gaps in spatial coverage and reduced intensity in some years, another potential source of uncertainty in the survey may result from vessel effects that may be introduced when research vessels conduct survey sets in an area typically covered by another vessel (see Brodie and Stansbury, 2007). This has not been a major issue in recent

surveys, however, there was some variation over 2009-2011 in the proportion of sets conducted by the CCGS *Teleost* and the CCGS *Alfred Needler* within Div. 3K during fall surveys. In addition, the CCGS *Teleost* conducted portions of the 2009 spring survey, which is atypical but has occurred infrequently in previous surveys.

The decision to attempt coverage of Div. 2H annually at the cost of excluding the deep-water strata in Divs. 3NO has some impact on the information available for various assessments. For both Greenland Halibut and the Northern shrimp stock (*Pandalus Borealis*) within Shrimp Fishing Area 5, annual coverage of Div. 2H will be beneficial in monitoring resource trends, and should permit enhanced capabilities when providing of management advice, particularly for the relatively short-lived shrimp. Alternatively, the loss of the deep-water survey coverage in Divs. 3NO will have some impacts on the available data for traditionally important commercial species (eg. Greenland Halibut, Witch Flounder and Grenadiers), but the survey information from these areas is not an essential part of the assessment of any of these species. It is imperative that any assessments relying upon either stratified mean numbers or mean weights per tow computed using results over all of Divs. 3NO investigate the impact that the removal of this portion of the survey area will have on these time-series.

Division 2H is covered at the beginning of the fall survey in early October, and is currently allocated approximately 80 sets. Although coverage of the deep-water in Divs. 3NO has been cancelled (approximately 50 planned sets), a concern is that the survey design at present has very limited scope for further cutbacks when survey delays inevitably arise. In the recent past, Division 3M, the inshore strata of Divs. 3KL, and the deep-water portion of Divs. 3NO were routinely cancelled in order to preserve the continuity of other areas with long-standing coverage considered more crucial to stock assessment. In the fall of 2011, none of these areas were covered (of the three, only the Div. 3KL inshore strata were planned) and due to delays arising from vessel mechanical problems compounded by unusually poor weather, significant reductions to the number of planned sets in Divs. 2J3KL were required mid-survey. Given the current rate of survey time lost and the fact that a third research vessel is no longer available to assist in survey coverage when problems arise, it is possible that such in-situ reductions may be more frequent in the near future. Any loss of coverage in the areas presently having long-standing time series is likely to have adverse bearing on the stock assessments of multiple species.

Conclusion

Extensive mechanical delays during the 2009 - 2011 fall surveys resulted in reduced survey coverage interchange of research vessels outside of their normal area coverage pattern, and have extended the time required to complete surveys of the individual divisions. The number of survey sets completed in the fall of 2009 and 2011 were relatively low, and some of the survey area was not covered. Recent spring surveys have generally been fully completed with limited coverage issues. Deficiencies in these surveys combined with those over 1995-2008 (see Brodie and Stansbury, 2007, Healey and Brodie, 2009) impact the assessments of many groundfish and invertebrate stocks to varying degrees, uncertainties which are typically not factored into the assessment results nor management advice.

Acknowledgements

The Canadian multi-species survey dataset would not exist without extensive efforts on the part of the Fisheries and Oceans scientific sampling teams as well as the crews of the CCGS *Teleost* and CCGS *A. Needler*. Also, we thank David Orr (DFO, St. John's, Newfoundland) for maintaining a survey summary document, which expedites analysis of the survey data, and Gus Cossitt (DFO, St. John's, Newfoundland) for producing Figures 1-8.

¹ CCGS *A. Needler* conducted 47 sets in Divs 3NO.

² CCGS *Teleost* conducted 40 sets in Div. 3L.

³ CCGS *Teleost* conducted 43 sets in Div. 3L.

⁴ CCGS *A. Needler* became the primary ship for spring surveys in 2009.

⁵ CCGS *Teleost* conducted 81 sets in Div. 3L.
