Abstract

A stratified random bottom trawl survey on Flemish Cap was carried out on July - August 2011, covering the bank up to 1460 m depth (800 fathoms). The survey was carried out on board R/V Vizconde de Eza, using a Lofoten bottom trawl gear, and 128 haul were done, 79 of them in the region with less than 730 m depth. Survey results are presented and compared with results of previous surveys in the series since 1988. Biomass and abundance indices are provided for main commercial species, as well as age composition for cod, American plaice, Greenland halibut, and roughhead grenadier.

KEYWORDS: Survey, Flemish Cap, Cod, American plaice, Redfish, Greenland halibut, roughhead grenadier.

Introduction

The survey on Flemish Cap was carried out on board R/V Vizconde de Eza. A total of 128 valid bottom trawls were made up to a depth of 1460 m (800 fathoms) (Figure 1). The survey covered adequately 31 of the 32 selected strata of the bank; only one haul was done in stratum 17. A synoptic sheet of the survey with vessel and gear characteristics is shown in Table 1. This was the 24rd survey of the series initiated by the EU in 1988. All surveys had a stratified random design following NAFO specifications (Doubleday, 1981). Dates of the previous surveys were:

Year	Vessel	Valid tows	Dates	Year	Vessel	Valid tows	Dates
1988	Cornide de Saavedra	115	8/7 – 22/7	2000	Cornide de Saavedra	120	10/7 – 28/7
1989	Cryos	116	12/7 – 1/8	2001	Cornide de Saavedra	120	3/7 – 20/7
1990	Ignat Pavlyuchenkov	113	18/7 – 6/8	2002	Cornide de Saavedra	120	30/6 – 17/7
1991	Cornide de Saavedra	117	24/6 – 11/7	2003	Vizconde de Eza	114	2/6 – 27/7
1992	Cornide de Saavedra	117	29/6 – 18/7	2004	Vizconde de Eza	124-177 ¹	25/6 – 2/8
1993	Cornide de Saavedra	101	23/6 – 8/7	2005	Vizconde de Eza	117-176	2/7 – 21/8
1994	Cornide de Saavedra	116	6/7 – 23/7	2006	Vizconde de Eza	115-179	1/7 – 26/7
1995	Cornide de Saavedra	121	2/7 – 19/7	2007	Vizconde de Eza	117-174	23/6 – 19/7
1996	Cornide de Saavedra	117	28/6 – 14/7	2008	Vizconde de Eza	110-167	21/6 – 19/7
1997	Cornide de Saavedra	117	16/7 – 1/8	2009	Vizconde de Eza	119-178	23/6 – 20/7
1998	Cornide de Saavedra	119	17/7 – 2/8	2010	Vizconde de Eza	97-153	22/6 – 21/7
1999	Cornide de Saavedra	117	2/7 – 20/7	2011	Vizconde de Eza	79-128	29/6 – 9/8

1) Up to 730 m deep (400 fathoms) – up to 1460 m deep (800 fathoms)

Previous survey report was presented by Casas and González Troncoso (2011).

As in previous years, strata 26, 27 and those in the Beothuk knoll (strata 35-39) were excluded due to previous records that indicate they were unsuitable for trawling.

Fishing was interrupted from 14 to 28 July due to mechanical breakdown, and 2-5 August to go ashore.

Results

Biomasses of main species in past surveys estimated by swept area method (tons) are:

year	cod	American plaice	redfish	Greenland halibut	roughhead grenadier	shrimp
Strata 1-19 120-730 m	1988	40 839	16 046	188 331	6 926	2 009

Values for surveys before 2003, when RV Cornide de Saavedra was used, are transformed to their equivalences for RV Vizconde de Eza following the accepted calibration among the two vessels (González Troncoso and Casas 2005). From 2004 onwards, abundances are calculated for 19 shallowest strata covering the bank up to 730 m deep, as it was done in previous years, and for 32 strata up to 1460 m deep.

Taking into account that the number of hauls done was about 2/3 of the target, the question was raised on the likeness of the current results with previous ones. Biological sampling was completed at the same level than usual, so this reduction in haul numbers only affects to those results being dependent of mean number per haul, e.g. the numbers at age. In those cases, with 2/3 of target hauls, expected variance of the results would be 3/2 higher than if full target hauls were available; the expected mean being the same. This 50% increase in variance, which is also 22% of the standard error, should be compared with the standard deviation of the variance to verify if it is inside the accepted deviation range or not. Even analytical values for the standard deviation of the variance were not available, their distribution was explored in one case study: cod abundance at age. Figure 2 shows the relationship mean-variance for numbers at age in each survey of the series since 1988. Mean and variance of the abundance at age in each survey were calculated by bootstrap at three levels: hauls, length distribution and otoliths ageing. Results indicate that the 2011 points are not out of the range of distribution of the same figures in other years, and it is interpreted as the reduction in number of hauls in 2011 did not affect the precision of estimates for cod abundance at age, used as an example.

Intermediate size haddock appears in last years in Flemish Cap as a consequence of two abundant year-classes, those of 2006 and 2007. The stock in 2011 comprised ages 4 and 5 in the rough proportion of 2/3 and 1/3 respectively. Having no new recruitments, the stock may not increase. The stock concentrates on the shallowest part of the bank, strata 1 and 2. The occurrence of these species is quite occasional. Noskov (1983) reported the occurrence of haddock from the 1980 year-class; Konstantinov *et al.* (1985) proposed it was due to the entry of eggs from the Grand Bank transported by currents.

Cod

Mean catch per towed mile by strata and its standard error are presented in Table 2. Survey biomass, as calculated by the swept area method, is compared with results of previous years by stratum in Table 4. Survey biomass is compared with Russian survey results in the following table:

Year	EU (1)	Russia: (2)	(3)	Year	EU (1)	Russia: (2)	(3)
1983		23 070		1998	4 986	-	-
1984		31 210		1999	2 854	-	-
1985		28 070		2000	3 062	-	-

1997	9 966	-	-				

1) Biomass estimated from bottom trawl survey.

2) Biomass estimated from bottom trawl survey (Kiseleva and Vaskov 1994; Kiseleva 1996, 1997; Vaskov and Igashov, 2003).

3) Biomass estimated of bottom trawlable plus pelagic biomass (Borovkov *et al.* 1993; Kiseleva and Vaskov 1994).

Tables 3, 5, and 6 show length distribution, the age-length key and abundance at age by stratum respectively. Distribution of survey catches is presented in Figure 3. Evolution of biomass is illustrated in Figure 4.

The abundance at age along the series is shown in Table 7. The 1992 to 2003 year-classes failed almost completely. The abundances of 2004-2008 year classes are higher than in previous 12 years. The abundance of the 2009 year-class was the highest of those in previous recent years, and the 2010 one seems to be even higher based on results at age 1 in 2011.

Figure 5 shows length distribution over the years. It illustrates the abundance of the two youngest year-classes as well the sharp reduction of mean length at age two from 2010 to 2011. Cod growth increased in those years the stock biomass was at very low level; the situation seems to be reversed now due to the recovery of the stock.

American plaice

Mean catch per towed mile by strata is presented in Table 8. Survey biomass, as calculated by the swept area method, is compared with results of previous surveys in Table 10. This biomass is compared with Russian survey results in the following table:

year	EU	Russia ¹	year	EU	Russia ¹
1983		8 900	1998	3 437	
1984		7 500	1999	2 585	
1985		7 800	2000	1 606	
1986		20 200	2001	2 404	
1987		9 300	2002	2 049	548
1988	16 046	6 500	2003	2 286	1 398
1989	14 047	5 000	2004	3 525	
1990	11 983	1 200	2005	2 760	
1991	10 087	14 400	2006	1 691	
1992	8 656	1 200	2007	1 053	
1993	7 861	2 700	2008	1 766	
1994	8 227		2009	1 442	
1995	6 785		2010	2 446	
1996	4 098		2011	4 084	tons
1997	3 026				

1) Rikhter *et al.* 1991; Borovkov *et al.* 1992, 1993, 1994; Vaskov and Igashov, 2003.

Tables 11, 12 and 13 show length distribution, the age-length key and abundances at age by stratum. Distribution of survey catches along the series is presented in Figure 6. Biomass evolution is illustrated in Figure 7.

Table 9 shows the abundance at age. Fish aged 6 or more roughly correspond with fishable biomass. Results indicate two periods for recruitment, and a change from an upper abundance level to a lower one. The 1991 year-class was the first weak cohort. The 2006 year-class is the more abundant since 1991, but its abundance is only intermediate. Recruitment for later year-classes seems to be weaker; too weak for a quick recovery of the stock.

Figure 8 shows length distribution over the years. It illustrates the lack of recruitment that occurred for many years, and how most recent year-classes are weaker than those at the beginning of the series.

Redfish

All redfish catches were classified by species. The group named *juvenile* contains those individuals of small size for which routine classification was not possible. The 15 cm maximum length is a good reference for this group, but it was never used as a criterion. The skill required to identify the species increased over the years, so the group *juvenile* was not uniform, but it is maintained for practical reasons.

Survey biomass by strata of *Sebastes marinus*, *S. mentella*, *S. fasciatus* and the *juvenile* group are presented in Table 14. Table 15 shows the total survey biomass by year in the strata up to 730 m deep (400 fathoms) and up to 1460 m, even differences are at a minimum.

For the whole bank, tables 16, 17, 18 and 19 show length distribution for the four groups. Catches per haul distribution for the three species and juveniles are presented in Figure 9. Evolution of biomass is shown in Figure 10, which illustrates the highest level since 2004 and the decline after the 2006-2008 high.

Greenland halibut

Mean catch per towed mile by strata and its standard error are presented in Table 22. Survey biomass is compared with results of previous surveys in Table 23. Catch per haul distribution is presented in Figure 11. Evolution of biomass is shown in Figure 12.

For the whole bank, length distribution, age-length keys and abundance at age are presented in Tables 24, 25 and 26, respectively. Abundance at age along the series is presented in Table 27.

Roughhead grenadier (*Macrourus berglax*)

Mean catch per towed mile by strata and its standard error are presented in Table 28. Survey biomass, as calculated by the swept area method, is compared with results of previous years by stratum in Table 29.

Tables 30, 31 and 32 show length distribution, the age-length key and abundance at age by stratum respectively. Distribution of survey catches is presented in Figure 13. Evolution of biomass is illustrated in Figure 14.

Survey biomass along this series for the 19 shallowest strata and the whole 32 strata were:

year	1-19	year	1-19	1-32
1988	2 009	2000	1 047	
1989	871	2001	2 079	
1990	852	2002	1 211	
1991	1 335	2003	2 348	
1992	1 577	2004	3 597	17 783

Table 1 – Technical data of the 2011 survey.

Procedure	Specification
Vessel	R/V Vizconde de Eza
GT	1 400 t
Power	1 800 HP
Mean trawling speed	3.5 knots (3.0 knots in more than 1000 m depth)
Trawling time	30 minutes effective time
Fishing gear	type Lofoten
footrope / handrope	31.20 / 17.70 m
footgear	27 steel bobbins of 30 cm
vertical opening	3.0 m (SCANMAR)
warps	100 meters, 45 mm, 200 Kg/100m
trawl doors	polyvalent, 850 Kg
wire length	$26.712 \times \text{depth echo sounder (m.)}^{0.6268}$.
mesh size in cod-end	35 mm
Type of survey	Stratified sampling
Station selection procedure	Random
Criterion to change position of a selected tow	- Unsuitable bottom for trawling according to ecosounder register. - Information on gear damage from previous surveys.
Criterion to reject data from tow	- tears in cod-end - severe tears in the gear - less than 20 minutes tow - bad behaviour of the gear
Daily period for fishing	6.00 to 22.00 hours
Species for sampling	All fish, squid, shrimp, and other invertebrates
Species for age determination	Cod, American plaice, redfish (<i>Sebastes mentella</i>), Greenland halibut and Roughhead grenadier (<i>Macrourus berglax</i>).
