P. O. Box 5667, St. John's, Newfoundland, Canada A1C-5X1

Abstract

Cod in Divisions 3NO inhabit the southern Grand Bank of Newfoundland. The stock declined dramatically during the mid-1980's and although at a low level, has experienced an improvement in recent years. Estimates from a population model utilizing the ADAPTive framework (Gavaris 1988) indicate the spawner biomass has doubled since 2010. However, the 2013 estimate of 25,000 t still only represents 42% of B_{lim} (60,000 t). Fishing mortality in the last 5 years has been less than 0.1 for ages 4-6 and amongst the lowest in the time series. The relatively strong 2005 and 2006 year classes observed in the previous assessment continue to be strong in 2013 and the fact that these cohorts have entered the spawner biomass is responsible for the sharp increase in this index. More recent year classes, however, are not as strong. Stochastic projections indicate the stock will increase in the next 3 years but there is >95% probability that the stock will remain below B_{lim} by 2016.

Introduction

The Divisions 3NO cod stock occupies the southern part of the Grand Bank of Newfoundland. Fish are distributed over the shallower parts of the bank in summer, particularly in the Southeast Shoal area (Div. 3N), and on the slopes of the bank in winter when cooling occurs. Some seasonal mixing between fish in Division 3O and Subdivision 3Ps may occur. This stock has been under moratorium to all directed fishing both inside and outside the Regulatory Area since February 1994. In 1998 the Scientific Council Report recommended that there should be no directed fishing for cod in Div. 3N and 3O in 1999 and that by-catches in fisheries targeting other species should be kept at the lowest possible level. All subsequent assessments have re-iterated this advice.

The 2007 assessment of this stock suggested that catch levels coupled with poor recruitment were resulting in high fishing mortality and impeding stock recovery. The 2010 assessment reported very low fishing mortality in 2008-09 and signs of improved recruitment. This assessment updates the status of the stock, based primarily on a population model incorporating Canadian spring and fall research vessel surveys conducted in Div. 3NO. Population and spawner stock biomass estimates for 1959-2013 are provided from ADAPT utilizing the catch at age and calibrated using three Canadian research vessel surveys.

Nominal catch and catch at age

Catches from this stock peaked at 227,000 tons (t) in 1967, mainly by the former USSR and Spain, but declined steadily thereafter to 15,000 t in 1978. From 1979 to 1991 catches ranged from 20,000 to 50,000 t (Table 1, Fig. 1). A consecutive decline in TAC's in the early 1990's reduced catches to a level of about 10,000 t in 1993 the last full

year of a directed fishery. Total catches since the moratorium (Table 1, Fig 1), increased from 170 t in 1995, peaked at about 4 800 t in 2003 and have been between 600 t and 1100 t since that time. The catch in 2012 was 734 t.

Length frequencies for 2010-2012 were available from Canadian, Spanish (González-Costas et al., MS 2011, 2012, 2013), Portuguese (Vargas et al., MS 2011, 2012, 2013) and Russian (Pochtar and Fomin MS 2012, Pochtar et al. MS 2013, Skryabin and Pochtar MS 2011) otter trawl fisheries. Due to considerable deficiencies in the number of aged otoliths from commercial catches (Table 5), the catch-at-age for these years was constructed by applying Canadian survey age length keys to the available length sampling from all countries. This has been the typical approach used for this stock when faced with sampling deficiencies (Table 5). In 1996, 1997, and 1998 the sampling was considered to be inadequate to develop a catch-at-age. An approach for developing catch at age for this period based on using an average partial recruitment pattern is presented in Stansbury et al. (1999). For 1999 and 2000 there are also gaps in the data but through the use of sampling collected by other contracting countries and by making use of Canadian research vessel survey age length keys, the catch at age was estimated. The catch at age time series reveals that ages 3-6 have dominated the catch for this stock (Table 6, Fig. 2).

Inadequate sampling has also presented problems historically for computing mean weight at age. To fill the 1996-1998 gaps, a geometric mean was computed at each age, using the three nearest non-zero values on either side of the three year window (Table 7).

Research vessel survey data

Stratified-random bottom trawl surveys have been conducted in spring by Canadian research vessels in Divs. 3N and 3O since 1971 and 1973, respectively, with the exceptions of 1983 in Div. 3N, and 1974 and 1983 in Div. 3O. The stratification scheme used for these surveys is based on depth (Fig. 3, Table 2). The surveys from 1991 onwards covered areas to a maximum of 732m (400 fathoms) but prior to this only covered to a maximum of 367m (200 fathoms). In 2006 survey coverage was incomplete and the 2006 spring survey is not considered an index of population size. Surveys from 1971 to 1982 were conducted by the research vessel *A.T. CAMERON* and those since 1984 were conducted primarily by the *WILFRED TEMPLEMAN* or its sister ship *ALFRED NEEDLER* (Table 3).

Autumn surveys have been carried out in Divisions 3NO from 1990 to 2008 using the *WILFRED TEMPLEMAN* for strata less than 732 m. Starting in 1995 the *Teleost* was used for sampling strata greater than 732m to a maximum depth of 1463m (800 fathoms), but coverage has not been consistent in these greater depths. Because of vessel difficulties in 1996 the *ALFRED NEEDLER* conducted the survey in strata less than 732m. In 2009 the autumn survey was conducted by the *ALFRED NEEDLER* with only partial coverage of Div. 3N strata greater than 732m by the *Teleost*.

In the autumn of 1995, the Campelen 1800 shrimp trawl with rockhopper footgear was introduced in the Canadian groundfish survey, replacing the Engel 145 Hi-rise trawl that had been previously used. The Campelen trawl is towed at 3.0 knots for 15 min instead of 3.5 knots for 30 minutes in the case of the Engel trawl. The selectivities of the two nets were estimated in comparative fishing experiments in 1995 and 1996 and were found to be markedly different, with the Campelen being far more effective at catching small cod and slightly less effective at catching large cod (Warren 1997; Warren et al. 1997). Conversion of Engels catches to Campelen equivalent catches are reported by Stansbury (1996, 1997).

Abundance and biomass estimates for these surveys are presented in Tables 8-15 and are plotted for the index strata (<200 fathoms) in Figs. 4-5. Spring and Autumn distribution plots are provided in Figs. 6 and 7 respectively. Abundance and biomass have been extremely low in both Div. 3N and Div. 3O from 1994 to about 2006. Levels have been slightly higher after 2006. The swept area survey biomass estimate from index strata (<200 fathoms) surveyed in 3NO combined for 2012 spring and autumn are about 80,000 t and 99,000 t respectively.

The mean numbers per tow at age for the index strata (< 200 fathoms) in 3NO combined are given in Table 16 for the spring survey and Table 17 for the autumn survey, and are plotted in Fig. 8 (age aggregated). Both the spring and autumn indices were extremely low from 1994-2006. MNPT increased for both surveys for the 2007-2009 period but have since declined. A large peak in the spring survey in 2009 was influenced by two very large fishing sets of ~6000 fish. An index derived from a juvenile flatfish survey conducted by Canada from 1989 to 1994 is presented in Table 18.

Fixed station grid surveys conducted in July by a Canadian based fishing company in cooperation with the Canadian Department of Fisheries and Oceans were available for the period 1996 to 2004 for Div. 3NO and are described in Maddock Parsons et al. (MS 2005). Catch rate of cod (kg/hour) increased from about 70 kg in 1997 to 193 kg in 1999, declined sharply to about 70 kg in 2000 and was stable to 2002. Catch rate declined to the lowest level in the time series at about 36 kg in 2004. These surveys have been discontinued.

Stratified-random surveys were conducted by Spain in the NRA area of Div. 3NO from 1995-2012 (Gonzales-Troncoso et al MS 2013). The series began utilizing a Pedreira trawl on the C/V Playa de Menduiña then converted to a Campelen 1800 trawl on the R/V Vizconde de Eza in 2001. The 1997-2000 data were converted into Campelen units by modeling data collected during comparative fishing trials in 2001. The data for 1995-1996 were not presented because the deeper strata in the area of coverage were not sampled. The mean weight per tow (Fig. 9) increased from 2.5 kg in 1997 to 19.5 kg in 1998 then declined to 3.5 kg in 1999. The index increased again to 37 kg in 2001 then declined rapidly to 11 kg in 2002 followed by successive declines to 4 kg in 2004. Since 2005 there has been a steady increase to the highest estimate in the series in 2011 at 155 kg. The 2012 estimate was quite a bit lower at 97 kg. The peaks in 1998 and 2001 were influenced by large single tows in those years. The abundance follows a similar pattern.

Analysis

Maturity at age

Annual proportion mature is modeled by cohort. This method has been used to estimate maturities of cod in NAFO Sub-Div 3Ps (Brattey et al. 2002), NAFO Divs. 2J+3KL (Lilly et al. 2003), and also for American Plaice in NAFO Divs. 3LNO (Morgan et al. 2002). A probit model with a logit link function was fitted by cohort to observed proportions mature at age from sampling conducted during Canadian spring surveys. The model fitted the data for all cohorts from 1953 to 2007, except for the 1991 and 2000 cohorts. The estimated age at 50% maturity (A50) ranged between 5.6 and 7.4 years for cohorts produced from the 1950's to 1980's (Fig. 10). Age at 50% maturity declined between 1980 and the late 1990's from approximately 6.8 to 4.5. The estimated proportion of females mature at age from the fitted cohort model is given in Table 19. Estimates for the 1991 and 2000 cohorts were produced by averaging the observed proportions from the two adjacent years. As the estimation is by cohort, special considerations are needed to fill the older ages for the starting years, and also for the younger ages for current years. These values were produced by averaging estimates from the 3 previous and 3 subsequent years for the appropriate age (shaded cells in table 19). Estimated annual maturities for 1975-2012 are plotted (Fig. 11) to show trends for selected ages. Estimated proportion mature for these ages increased up to the mid-2000's, and in most cases have shown a general decreasing trend since that time.

Sequential Population Analysis

Survey Indices: Cohort Tracking

The last thorough assessment of this stock utilized a sequential population analysis applying the ADAPT framework (Gavaris 1988) estimation of population size. Prior to the implementation of this analysis on the updated database, cohort tracking and consistency within the survey data was evaluated by a number of illustrative and standardized age-disaggregated plots. For each survey series that extended to 2012 in 3NO (Canadian Spring, Canadian Autumn) the following were evaluated: (a) age-disaggregated plots of mean number per tow 3NO, (b) pair-wise scatter plots and correlations of age-disaggregated survey data (log-scale) and (c) standardized proportions by age across years (SPAY) and by year across ages (SPYA). In the SPAY plots the annual index proportions were standardized at each age to have a mean of 0 and a variance of 1. For the SPYA plots a similar procedure was followed, but the proportions for each age were computed across years prior to standardizing by the mean and variance computed across all ages.

For the Canadian Spring survey the 1989 and 1990 year classes were the most dominant in the series from 1990 to 2008 (Fig. 12a) but at different ages. For example, the 1989 year class was dominant at ages 2, 4, 7, 9 and 10 whereas the 1990 year class was dominant at ages 3 and 8. The 2006 year class shows up very strong as age 3 in

2009 and the 2005 year class is strong at age 4 in 2009 and age 7 in 2012. pairwise plots and correlations (Fig. 12b) indicate generally good tracking between ages for cohorts.

For the 1990-2009 Canadian Autumn survey the 1989 and 1990 year classes were amongst the most dominant in the series (Fig. 13a) and also illustrate a similar pattern as the spring. The 1989 year class was dominant at ages except 7 whereas the 1990 cohort is only dominant at age 7, 8. The 1997 and/or 1998 cohorts were also very apparent at ages 3-9, something not so obvious in the spring series. A decline in density is also quite dramatic by age 5 for most cohorts. The pairwise plots and correlations (Fig. 13b) also indicate generally good tracking between ages for cohorts although correlations were not as good as in the spring.

Standardized indices by age for the Canadian Spring and Autumn surveys are compared in Fig. 14. The EU-Spain survey is also included for comparison. The results indicate generally good tracking for the Canadian surveys.

ADAPTive Framework

The catch at age (Table 6) was used in a sequential population analysis applying the ADAPT framework (Gavaris 1988). The catch for age 2 is from the NAFO SCR Docs series presented from 1988 to 1998. Zero catch was assumed for age 2 in years 1959-1987. Due to inadequate sampling of removals, total catch for 1996-1998 was proportioned by age using the average partial recruitment vector from 1990-93 (from a previous ADAPT run) with the fully recruited F estimated from a catch projection so as to match the observed catch (further details in catch-at-age section). Catches since that time have been based on fishery sampling although for some contracting parties constructing catch at age required using Canadian RV age-length keys (see table 5).

The ADAPT was calibrated with Canadian RV survey indices at age from spring 1984-2005 and 2007-2012, autumn 1990-2012 and a Canadian juvenile survey 1989-94 to estimate population numbers $N_{i,t}$,

where $i = 3$ to 12, for $t = 2013$ (10 parameters) and $i = 12$, for $t = 1994$ to 2012 (19 parameters),

and Catchabilities

- q_{1i} where $i = 2$ to 10 for the Canadian Research Vessel survey spring (RV1) (9 parameters)
- q_{2i} where $i = 2$ to 10 for the Canadian Research Vessel survey autumn (RV2) (9 parameters)
- q_{3i} where $i = 2$ to 10 for the Juvenile Research Vessel survey (RV3) (9 parameters)

The following structure was imposed:

- natural mortality was assumed to be 0.2,
- fishing mortality on the oldest age (12) set equal to the average F for ages 6 to 9 for years 1959-1993,
- no “plus” age class,
- equal weighting of all indices,
- no error in the catch numbers-at-age.

Input data were:

- Catch numbers at age,
- $C_{i,t}$ where $i = 2$ to 12 and $t = 1959$ to 2012 ,
- Canadian Research Vessel survey estimates of mean numbers per tow-at-age (Campelen or Campelen equivalent values),
- $RV_{1i,t}$ where $i = 2$ to 10 and $t = 1984$ to 2005 and 2007-2012, spring
- $RV_{2i,t}$ where $i = 2$ to 10 and $t = 1990$ to 2012, fall
- and Canadian juvenile Research Vessel survey estimates of mean numbers per tow-at-age (Yankee 41.5 shrimp trawl in August – September)
- $RV_{3i,t}$ where $i = 2$ to 10 and $t = 1989$ to 1994 .

The objective function minimized is

$$SS = \sum_{s,i,t} \{ \ln(RV_{s,i,t}) - \ln(q_{s,i} N_{i,t}) \}^2$$

where s= Survey 1 to 3 , i =age 2 to 10, t= year of survey.

This particular model formulation was selected since it follows the accepted VPA from the last assessment in 2010 and effectively deals with problems associated with zeros in the catch matrix at the age 12 (by estimating survivors at age 12 in these years). The statistics associated with the ADAPT output are given in Table 20. The mean square error of the residuals of the model fit was 0.617 based on an estimation of 56 parameters. For the survivors estimated in 2013, the relative error in the parameter estimates decreased with age from a high of 57% at age 3 to 28% at age 12. Relative bias was a high of 17% at age 3 decreasing to 4% at age 12.

The estimated survey catchabilities (q's) with associated standard errors are also provided in Table 20 and Fig. 15. Survey catchabilities (q's) generally decrease with age for all three surveys with the spring and autumn tending to having similar q's for ages 7-10. The Yankee 41.5 (juvenile survey) catchability for age 2 is more than three times that for the Campelen surveys.

Diagnostic residual plots from the ADAPT run are presented in Fig. 16-17. Overall the spring and autumn surveys show little pattern in the residuals, although there are some year effects. These are evident in the spring survey in 1987, 1993, 1996 and 1998 (mostly positive) and 1989, 1995, 2002 (mostly negative) (Fig. 16-17). The fall 1997 estimates have large negative residuals, particularly for ages 5, 6 and 7.

Bias-adjusted estimates of population numbers (Fig. 18) and fishing mortality at age (Fig. 19) are given in Tables 21 and 22 respectively. The age 2 value in 2013 is the geometric mean of the 2010-2012 age 2 estimates from the ADAPT. Population numbers remain low. There was a small increase between 2006-2008 but there has been a leveling or declining trend since that time. The recent improvement in recruitment from the 2005 and 2006 year classes has accounted for much of this increase (Fig. 20). The previously dominant 1989 year-class is no longer contributing to the VPA population (since 2001). The relatively strong 2005 and 2006 cohorts noted in the 2010 assessment continue to be strong in 2013. The strength of these year classes is still low relative to historic estimates. Fishing mortality (Table 22, Fig. 19) has been very low since 2008 (< 0.1) on the prominent age groups in the fishery.

Beginning of year mean weight-at-age calculated from the commercial catch is presented in Table 23. These weights are used to calculate biomass, given in Table 24. Stock biomass reached an historic low in 1995 before a period of marginal increase which peaked in 2001 and declined to 2004. Since then there has been a steady increase to 2013 which is the highest level since 1991. The maturities computed from the cohort model were applied to the population numbers to compute the spawner stock biomass (Table 25, Fig. 21). SSB has doubled since the 2010 assessment as the relatively strong 2005 and 2006 cohorts have become part of the spawner biomass. Current SSB is estimated to be about 25,100 t, which is approximately 42% of B_{lim} (60,000 t). This increase in SSB may be short-lived as subsequent year classes do not appear to be as strong.

Retrospective analysis

A retrospective analysis was conducted to investigate whether systematic trends were apparent in the population modeling. A 5 year period was chosen to evaluate whereby a complete year of data was removed, one year at a time in succession (for catch at age and survey indices at age), and the estimation with identical structure to the VPA formulation above was repeated for each case. There was very little evidence of a retrospective pattern for fishing mortality but more so for recruitment and SSB (Fig. 22).

Stochastic Projections

Simulations were carried out to examine the trajectory of the stock under two scenarios of fishing mortality: F=0, F=0.04 (the average F on ages 4-6 from 2010-2012). For these simulations the terminal year survivors from the ADAPT (i.e. Jan 2013 Population numbers), estimates of age by age relative error and the correlation matrix of population estimates were used. The following inputs were the basis of these projections:

Age	Estimate of 2013 population numbers ('000)	Relative error on population estimate	Weight-at-age mid-year (avg. 2010-2012)	Weight-at-age beginning of year (avg. 2010-2012)	Maturity-at-age (avg. 2010-2012)	PR rescaled relative to ages 4-6 (avg. 2010-2012)
3	1045.7	0.573	0.46	0.45	0.01	1.94
4	2244.9	0.426	0.68	0.53	0.06	1.36
5	2468.3	0.358	1.05	0.84	0.20	0.85
6	1512.0	0.306	1.73	1.31	0.54	0.79
7	4490.9	0.277	2.70	2.20	0.87	0.95
8	2289.4	0.255	4.04	3.62	0.98	1.27
9	754.9	0.264	5.73	4.69	1.00	0.59
10	558.4	0.263	5.21	5.53	1.00	1.24
11	140.3	0.265	8.12	6.07	1.00	0.46
12	54.9	0.278	9.85	8.62	1.00	0.06

Given the current estimate of SSB is well below Blim simulations were limited to a 3-year period. In addition, recruitment (at age 3) was only re-sampled from 1994-2012 as this represents a reasonable expectation of what has occurred under low stock sizes during the moratorium. The fishery selectivity (i.e. partial recruitment – PR) was rescaled to ensure these age groups would endure the projected fishing mortality.

At F=0 spawner stock biomass is estimated to increase and there is an 88% probability that SSB will remain under Blim by 2013 (Table 26, Fig. 23). At F=0.07 the population is estimated to grow more slowly. If the fishing mortality in 2010-2012 remains at the average estimated in 2007-2009 then yield is estimated to increase over the 3-year time period.

Conclusion

Fishing mortality on 3NO cod has been very low (<0.1) for the past five years and amongst the lowest values in the time series. Recruitment of the 2005 and 2006 year classes was strong relative to other recent year classes and these cohorts continue to be strong as they begin to mature and enter the SSB. Spawner biomass has doubled since the last assessment in 2010. The current estimate of spawner stock biomass is 25 000 t which is still well below the current best estimate of Blim (60,000 t).

Provisional² Includes an estimate of 4000 t deemed misreported to Div. 3L.³ Includes estimates by Canadian Surveillance and by NAFO Scientific Council.⁴ Catch could not be precisely estimated but is in the range of 4, 280 - 5, 460 tons⁵ There has been no directed fishery since February 1994.

Table 2. Details on the stratification scheme used for the assessment of 3NO cod.

Table 4. Cod landings (t) by month and gear from NAFO Divisions 3NO by Canada in 2010, 2011 and 2012.

Table 5. A review of sampling used to compile catch at age for 3NO cod from 1995 to 2009.
Highlighted years note use of Canadian RV age/length keys to some commercial catches

Sampling		Canada	Spain	Portugal	Other
1995	No Spanish sampling. Sampling available from Portuguese gill net and otter trawl fisheries	14/GN 60/LL	29	15/OT 15/GN	79
1996	No Spanish sampling. Sampling insufficient	19/OT 31/GN 47/LL 1 MWT Total 98	5	26/OT 6/GN	38
1997	Sampling insufficient	203/GN 83/OT 40/LL 2/MWT 329 Total		113	
1998	Some Canadian otter trawl frequencies and age samples but nothing for gillnets. Portuguese length frequencies but no aging.	185/OT 160/GN 50/LL 396 Total		95/OT	56
1999	Length and age sampling for Canadian by-catch was limited to the otter trawl fishery in 3N and 3O. Where deemed appropriate sampling was used for the adjacent division. Canadian catch at age was prorated by 135 t for catch with no sampling was available. Some monthly frequencies by division were provided by Portugal and these in conjunction with keys from the Canadian Spring RV surveys were used to partition the Portuguese and Spanish catch. Age composition by division was provided by Russia.	122/OT 351/GN 66/LL 2/ST 26/UK	3	322	26
2000	Length sampling for Canadian by-catch was limited to the otter trawl fishery in 3N and 3O. Age sampling was inadequate so spring and fall rv keys were used. Canadian catch at age was prorated for 77 t of catch with no sampling. Frequencies provided by Portugal and Spain were used with Canadian RV survey key to calculate catch for Portugal and Spain. Age composition by division was provided by Russia.	128/OT 29/GN 43/LL 7/UK	200	500	143
2001	Length sampling for Canadian by-catch was limited to the otter trawl fishery in 3N and 3O. However this comprised 85% of the Canadian catch. 89 t caught in other gears added to the overall Canadian, Spanish and Portuguese catch at age. Age sampling for Canadian catch adequate. Portugal provided catch by area and month and length sampling. Spain provided catch by division and length sampling. Portuguese catch at age compiled using monthly sampling and keys created from Canadian Spring and Autumn RV surveys using only data from strata straddling or outside 200-mile limit. Spanish catch at age compiled using yearly frequencies by division provided and a key created by combining the two RV keys. Russia provided catch at age for sampled fish. Estonian catch at age based on Russian data. Individual countries catch at age scaled to catch agreed on at June 2002 STACFIS meeting.	470/OT 24/GN 61/LL 4/SS	89/OT	392/OT	271
2002	Adequate length measurement from Canadian ottertrawl fishery by-catch. Canadian sampling of the gillnet by-catch is minimal however this gear accounts for less than 5% of the catch. With such small amounts being landed it's next to impossible to capture a representative sample. Longline by-catches makes up ~8 % of the Canadian catch and it is not sampled at all. Frequencies from Portugal, Spain and Russia were used with Canadian commercial keys to partition catch into catch at age.	370/GN 2933/OR	255/OT	8484/OT	9577/OT
2003	Adequate length measurement from Canadian ottertrawl fishery by-catch. However by-catch in other Canadian fisheries accounted for ~25% of the Canadian catch. This was poorly sampled and age distribution of this catch may not reflect reality. Ample length samples were provided by the Portugal and Russia. These were used in conjunction with Canadian Research survey keys to create catch at age for Russia and Portugal. Catch by Spain was partitioned using frequencies from Portugal. Catch by Norway, Lithuania and Estonia was partitioned using frequencies from Russia.	45/GN 86/LL 5437/OT		13236/OT	5291/OT
2004	Length sampling limited to Canadian by-catch in the otter trawl fishery. This sampling is sparse and should be improved as there are observers aboard the vessels fishing Yellow tail flounder. By-catch by other gears accounted for ~6% of the catch and this not sampled. Monthly and quarterly frequencies provided by Portugal and Russia were used in conjunction with Canadian Research Survey keys to create catch at age for Portugal, Spain, Russia and Estonia.	14/LL 2777/OT	905/OT	2333/OT	1508/OT
2005	Canadian ottertrawl fishery was adequately sampled providing frequencies and keys. Length frequencies provided by Spain and Russia were used in conjunction with Canadian Research Survey keys to create catch at age for Spain, Portugal, Russia and Estonia.	2/LL 4706/OT	6109/OT		125/OT
2006	Canadian cod bycatch was taken mainly in the ottertrawl and gillnet fishery for redfish and hake. Sampling was limited mainly to frequencies. Canadian autumn research keys were used. Frequencies provided by Portugal and Russia were used in conjunction with Canadian autumn research keys to compile catch at age for Portugal, Spain, Estonia and Lithuania.	44/GN 478/OT		3269/OT	125/OT
2007	Canadian cod by catch was taken in the ottertrawl fishery for yellow-tail, redfish and hake. The ottertrawl fishery was sampled by observers. About 40 % of the Canadian catch was taken in longline fisheries and no sampling exist for this catch	1457/ OT NO LL	401 (135 mm mesh)/OT No sampling for 280mm mesh	376 (130mm mesh)/OT; 18 (280mm mesh)/OT	811 /OT /Russian fishery
2008	Canadian cod by catch was taken in the ottertrawl fishery for yellow-tail, redfish and hake. The ottertrawl fishery was sampled by observers. About 25 % of the Canadian catch was taken in longline fisheries and no sampling exist for this catch	1796 OT NO LL	408 OT	41 OT for 30	519 OT
2009	Canadian cod by catch was taken in the ottertrawl fishery for yellow-tail, redfish and hake. The ottertrawl fishery was sampled by observers. About 20 % of the Canadian catch was taken in longline fisheries and no sampling exist for this catch. Canadian research survey keys used to age all catch	246/OT length and 24 aged fish	511(130m m, 3N)/OT; 98(280mm, 3N)/OT	1935 OT	
2010	Canadian cod by catch was taken in the ottertrawl fishery for yellow-tail and amounted to 109 t	90 commercial and 997 research ages	1354 measured	2467 130mm and 223 280mm mesh measured	171 measured
2011	Canadian cod by catch was taken in the ottertrawl fishery for yellow-tail and amounted to 54 t	23 commercial and 959 research aged	396 measured	5042 measured	100 measured
2012	Canadian cod by catch was taken in the ottertrawl fishery for yellow-tail and amounted to 26 t	1441 research ages	2411 measured	4484 measured

Table 8. Cod abundance (000's) from Canadian spring RV surveys in Division 3N. Both index strata and the most commonly fished deep strata are shown. The index strata are the basis for the assessment. Data for 1984-1995 have been converted to Campellan equivalent units. Values in brackets are estimates for non-sampled strata.

Table 10. Cod abundance (000's) from Canadian spring RV surveys in Division 30. Both index strata and the most commonly fished deep strata are shown. The index strata are the basis for the assessment. Data for 1984-1995 have been converted to Campellan equivalent units. Values in brackets are estimates for non-sampled strata.

Table 12. Cod abundance (000's) from Canadian Autumn RV surveys in Division 3N. Both index strata and the most commonly fished deep strata are shown. The index strata are the basis for the assessment. Data for 1984-1995 have been converted to Campellan equivalent units. Values in brackets are estimates for non-sampled strata.

Table 15. Cod biomass (t) from Canadian Autumn RV surveys in Division 3O. Both index strata and the most commonly fished deep strata are shown. The index strata are the basis for the assessment. Data for 1984-1995 have been converted to Campellan equivalent units. Values in brackets are estimates for non-sampled strata.

Table 17. Estimated proportions mature for female cod from NAFO Divs. 3NO from DFO surveys from 1975 to 2012 projected forward to 2015 and back to 1954. Estimates were obtained from a probit model fitted by cohort to observed proportions mature at age. When the model did not fit the data for a particular (cohort) (i.e 1991 and 2000 cohorts) the average of estimates for the same age group from adjacent years was used; dark shaded cells are averages extrapolated forward or backward from the same age group from 3 previous (or next) years.

Year	Age 1	Age 2	Age 3	Age 4	Age 5	Age 6	Age 7	Age 8	Age 9	Age 10	Age 11	Age 12	Age 13	Age 14

Table 23. Beginning of year mean weights at age calculated from the commercial catches for cod in Divisions 3NO.
Values in 2013 are the geometric mean of the previous three years.

Year\Age	3	4	5	6	7	8	9	10	11	12
1959	0.301	0.664	1.001	1.622	2.572	3.129	3.670	4.419	4.843	5.691

Table 27. Risk assessment of the probability of being below B_{lim} under various fishing scenarios. Yield is the median projected value.

Fishing Mortality	Yield			P(SSB<B _{lim})			P(SSB ₂₀₁₇ <SSB ₂₀₁₃)
	2014	2015	2016	2014	2015	2016	
F=0	-	-	-	>95%	>95%	>95%	<5%
F _{SQ} =0.04	1214	1114	1175	>95%	>95%	>95%	<5%

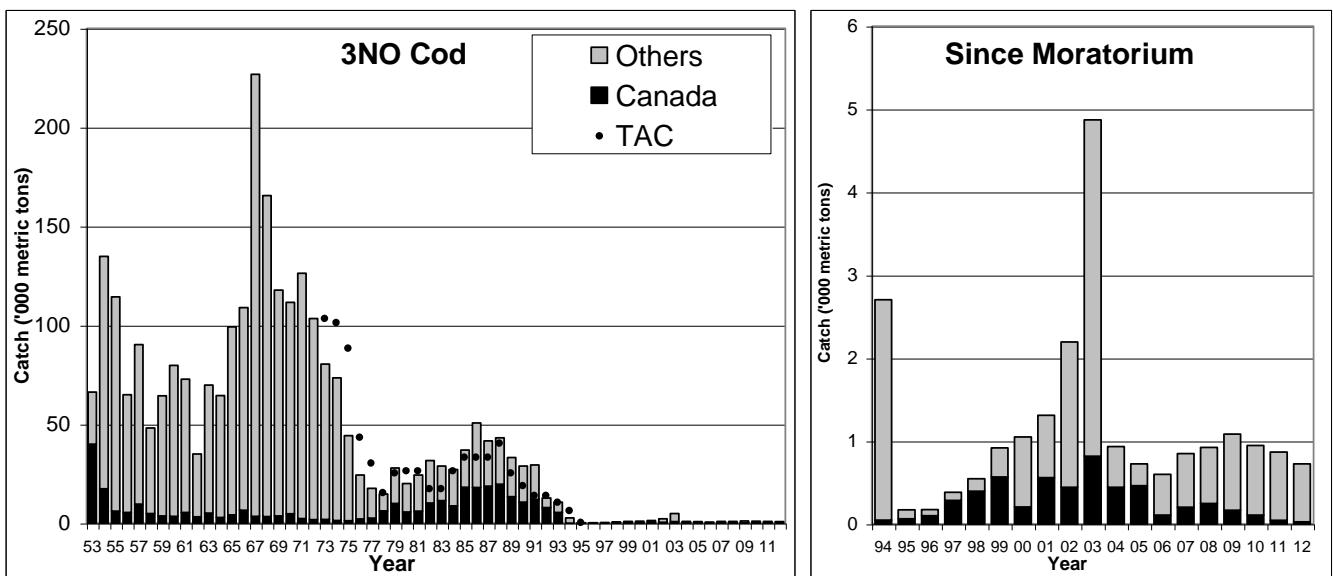

Fig. 1. Catches of cod in NAFO Div. 3NO from 1953-2011. Panel on right for years since the moratorium in Feb. 1994.

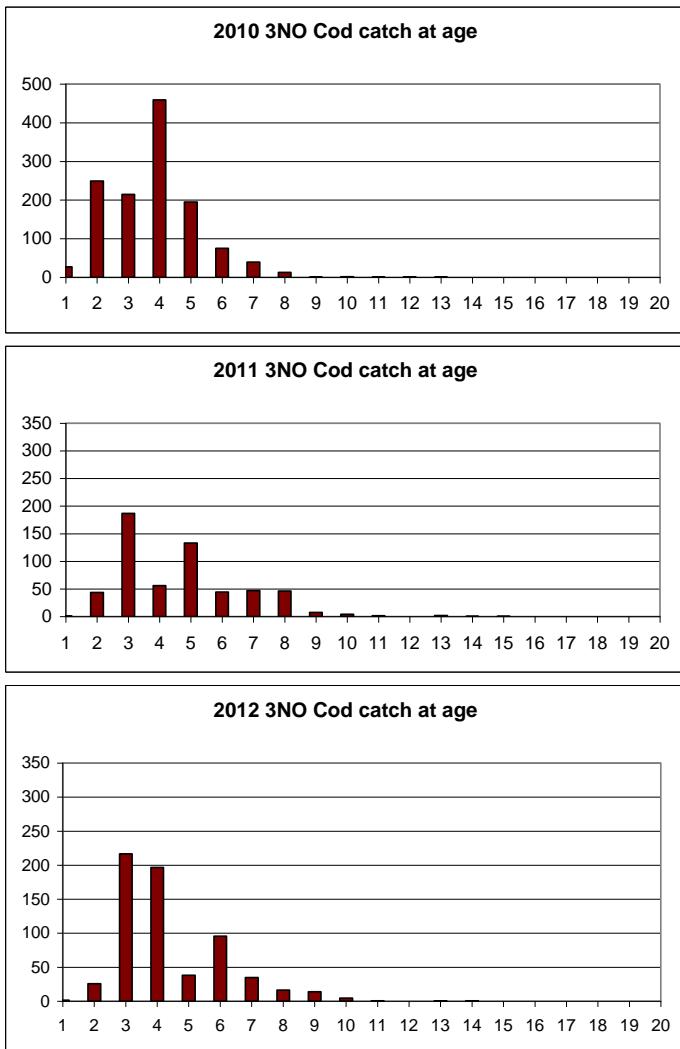

Fig. 2. Plot of Div. 3NO Cod catch-at-age for 2010-2012

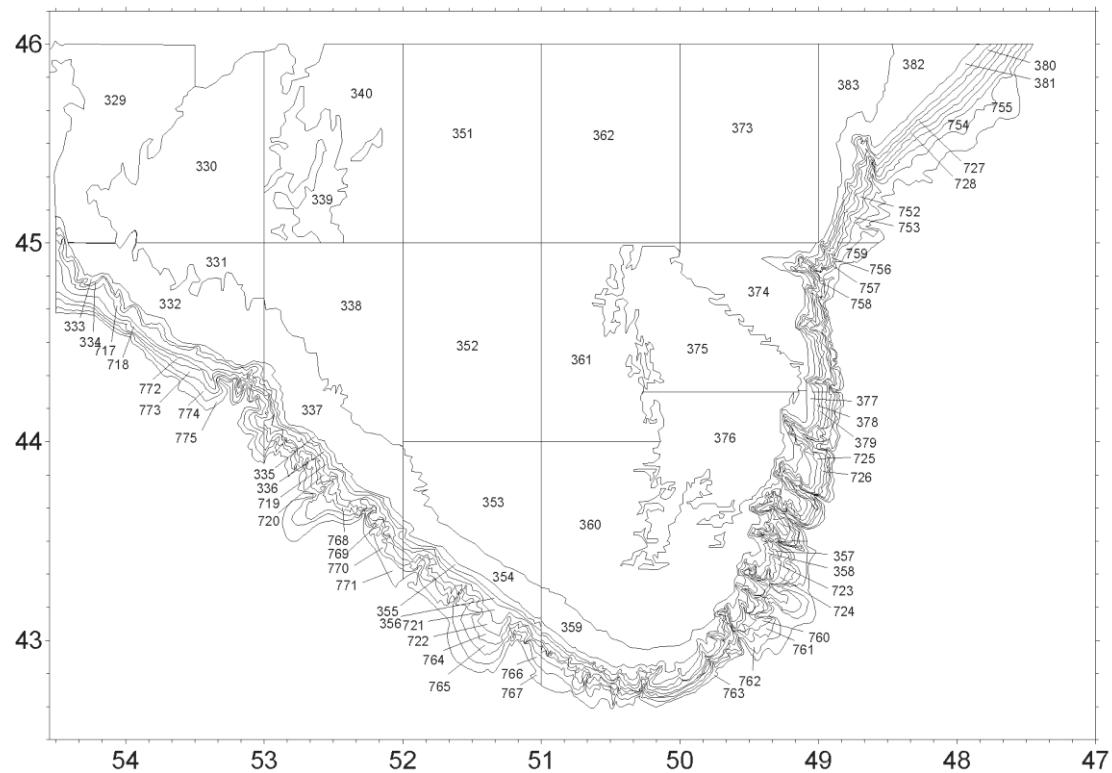

Figure 3 - Stratification scheme for Divisions 3NO.

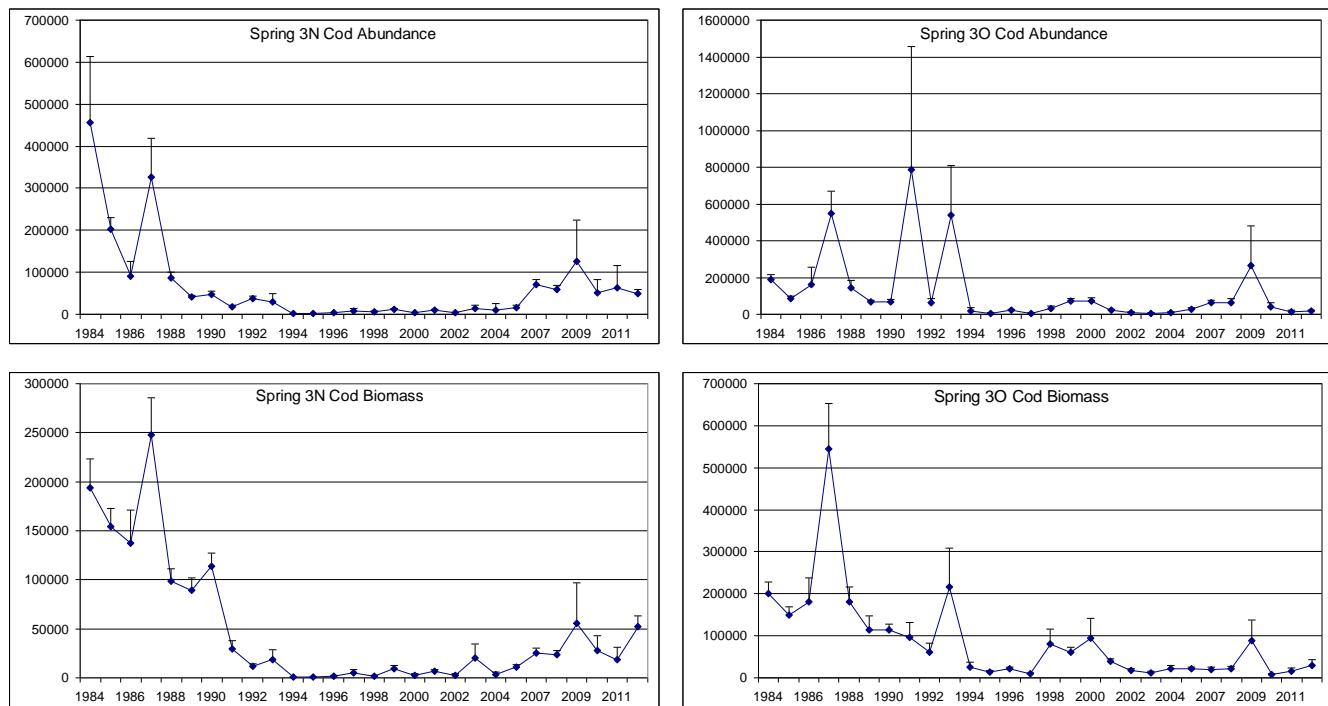

Figure 4 – Abundance (000's) and biomass (t) for the Canadian Spring Research Vessel survey series with 1 standard deviation for strata<200 fathoms.

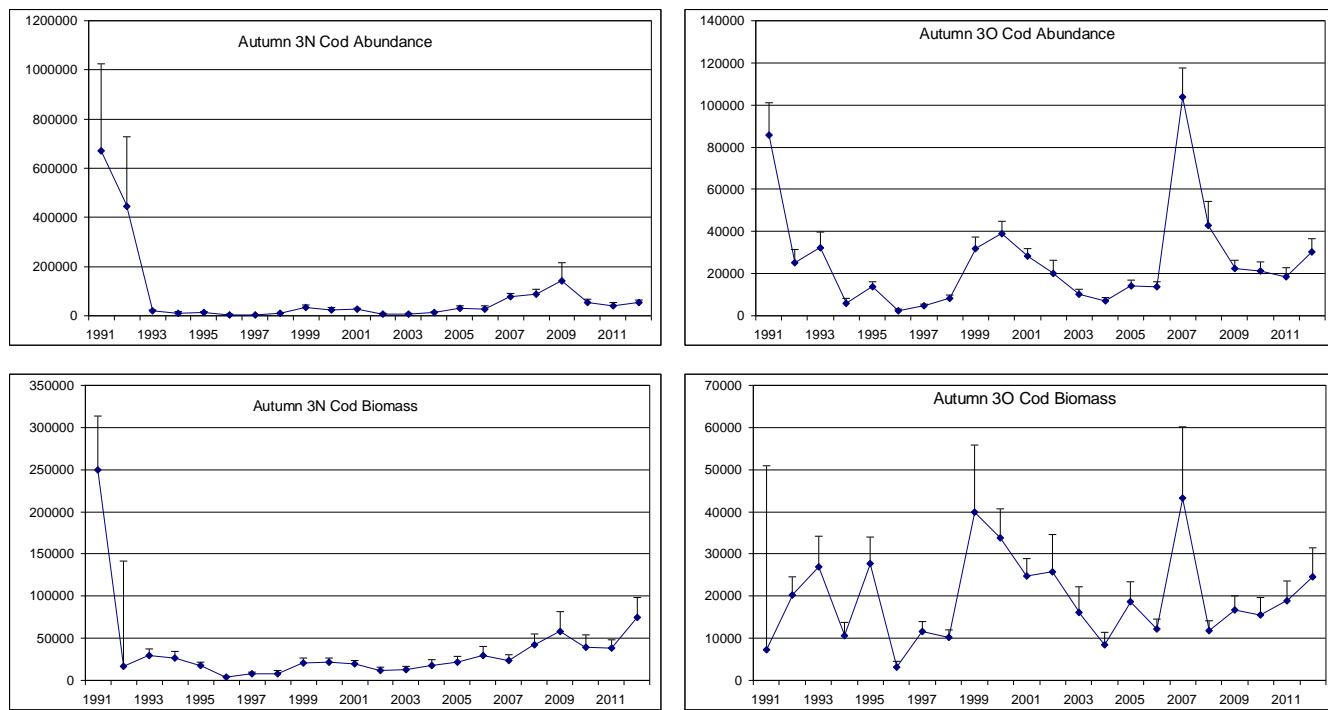

Figure 5– Abundance (000's) and biomass (t) for the Canadian Autumn Research Vessel survey series with 1 standard deviation for strata<200 fathoms.

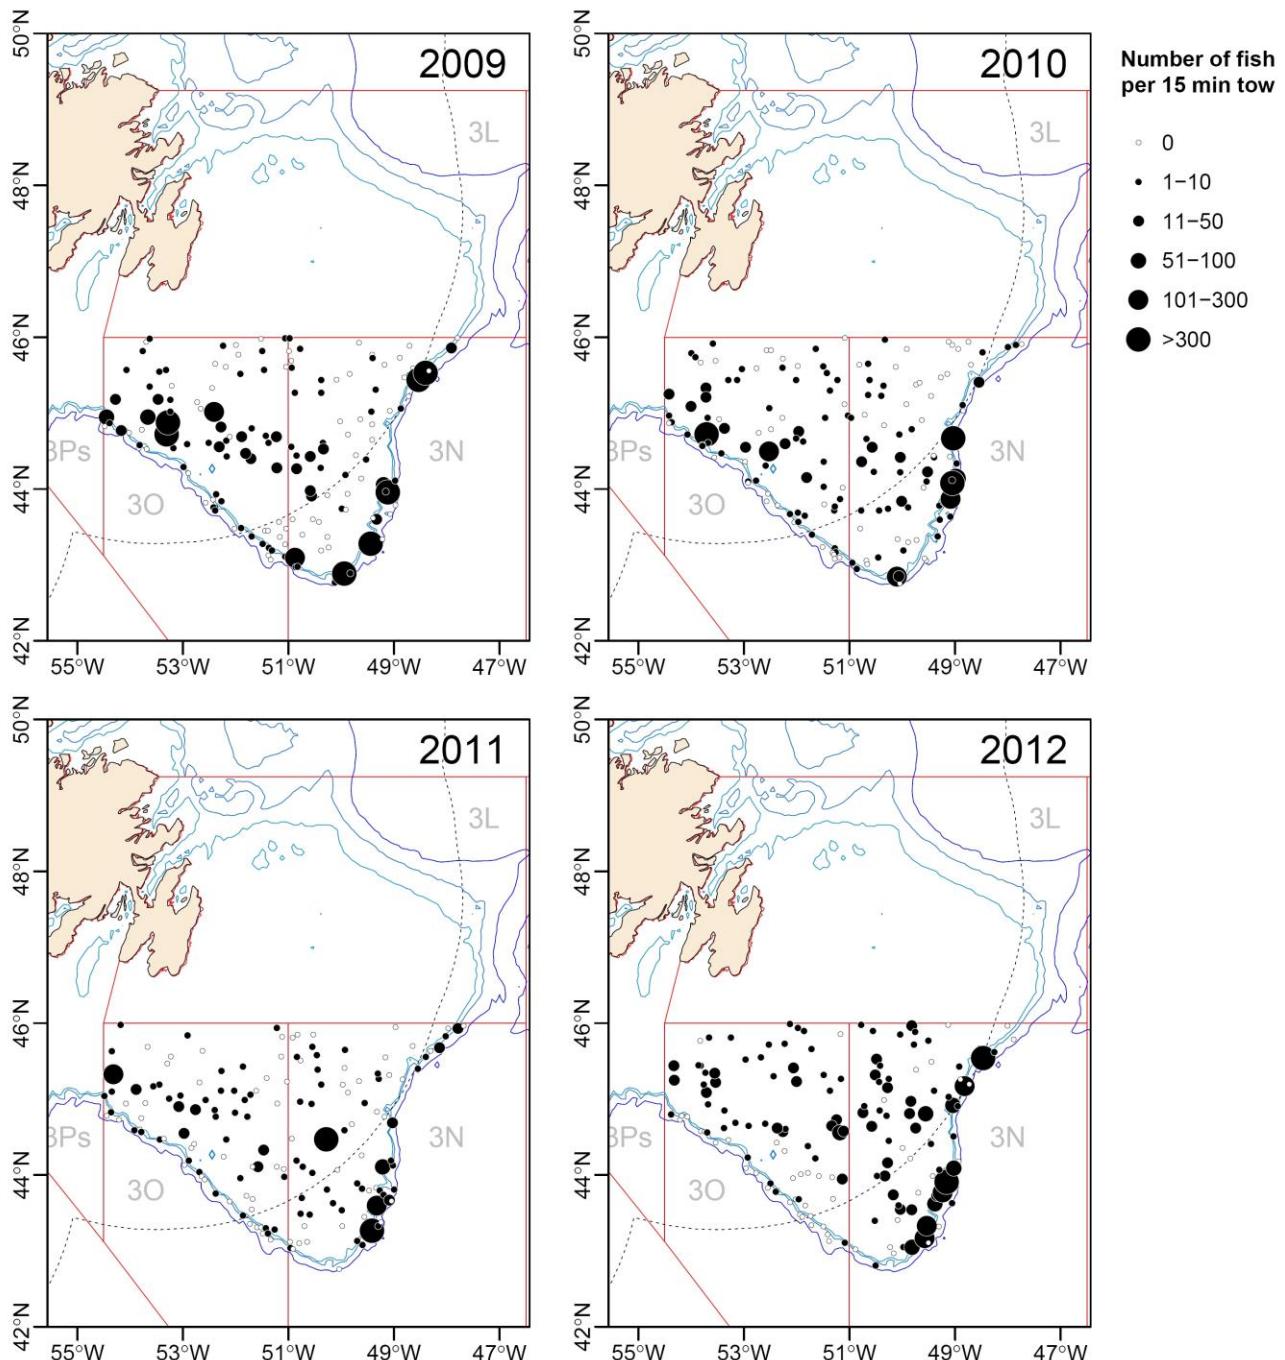

Figure 6. Distribution plots for Divs. 3NO cod from the Canadian Spring survey.

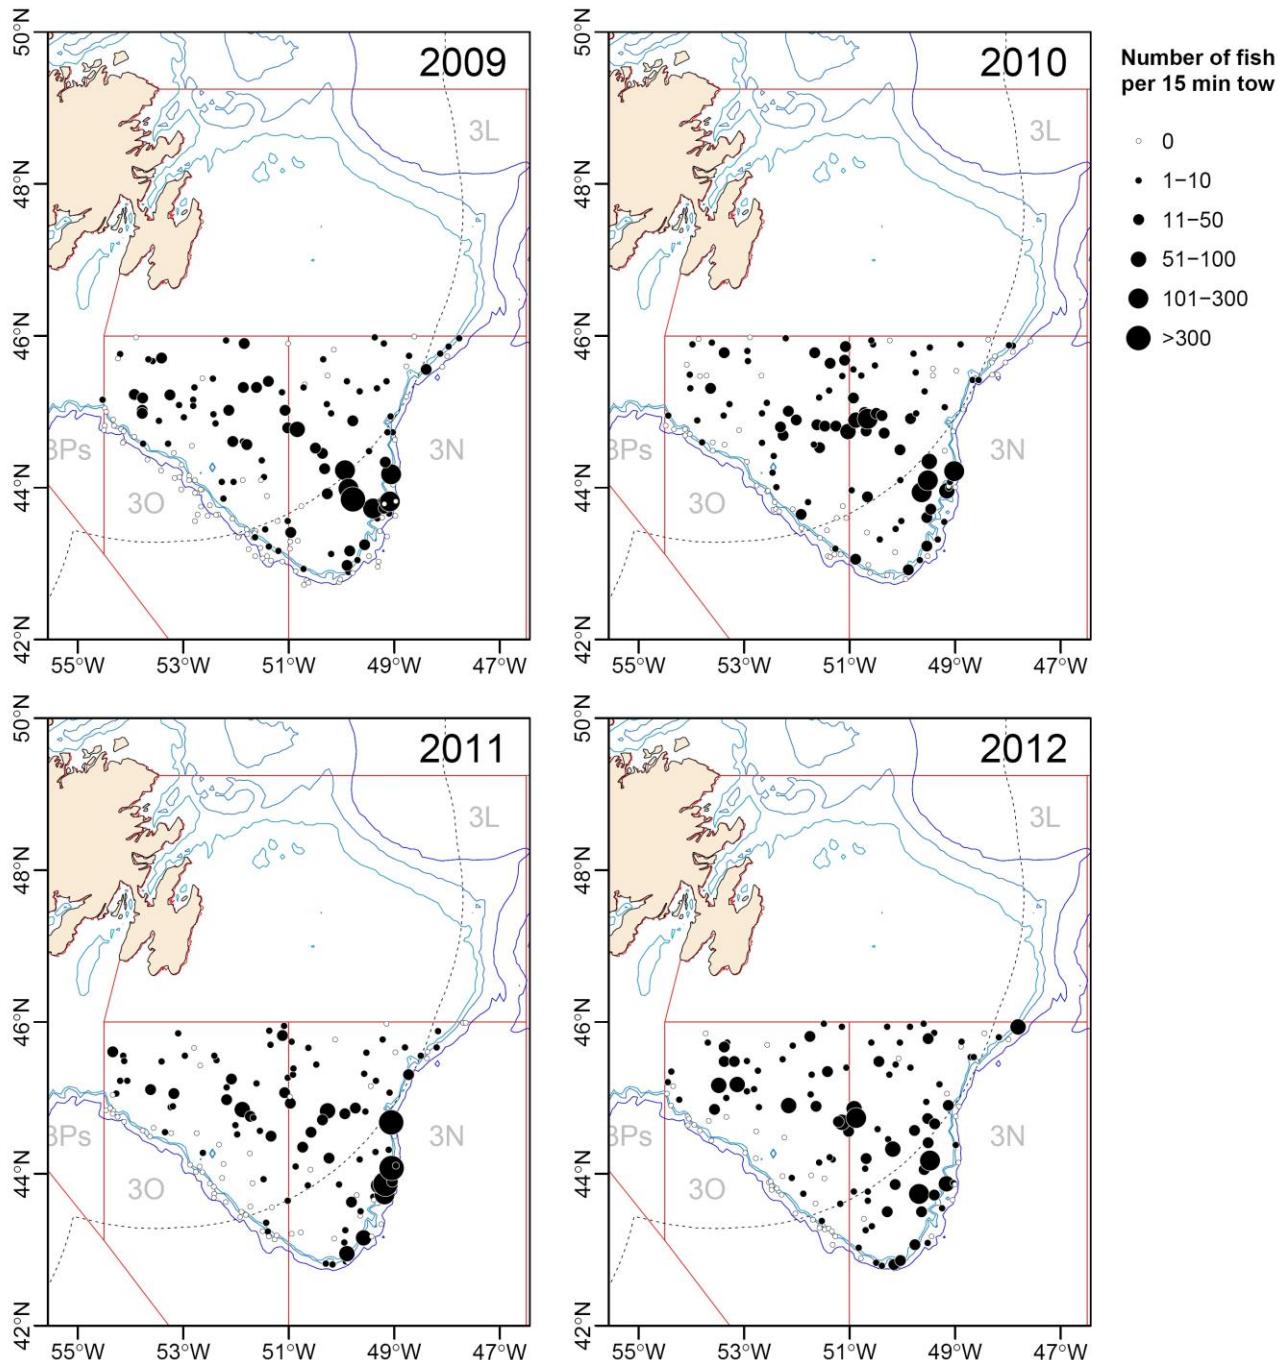

Figure 7. Distribution plots for Divs. 3NO cod from the Canadian Autumn survey.

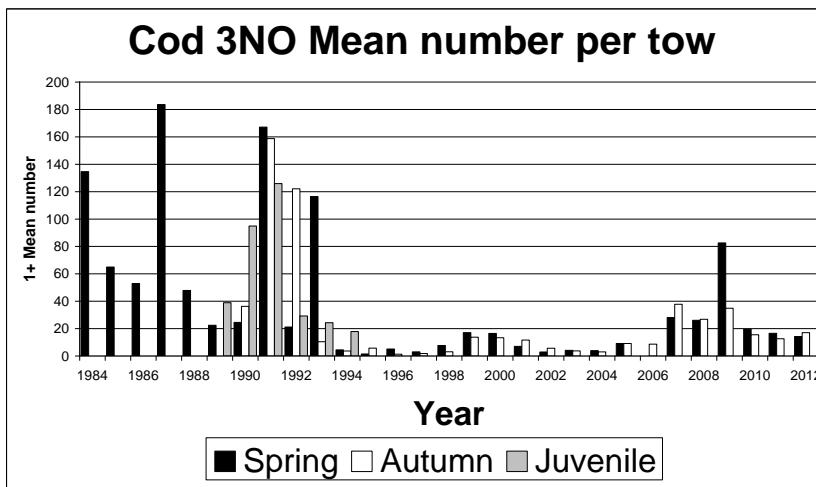

Fig 8. Spring and autumn Canadian RV estimates of 1+ mean number/tow of cod in Divisions 3NO

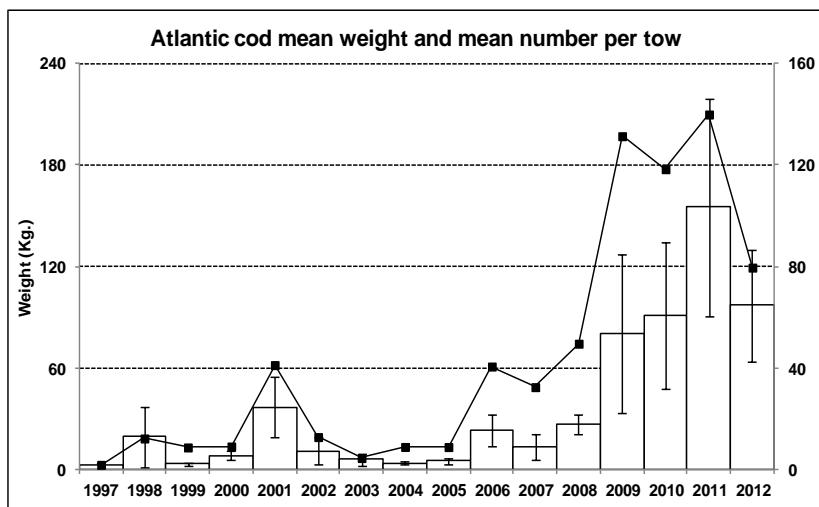

Fig. 9. Mean number and weight (kg) per tow from Spain Div. 3NO surveys of the regulatory area .

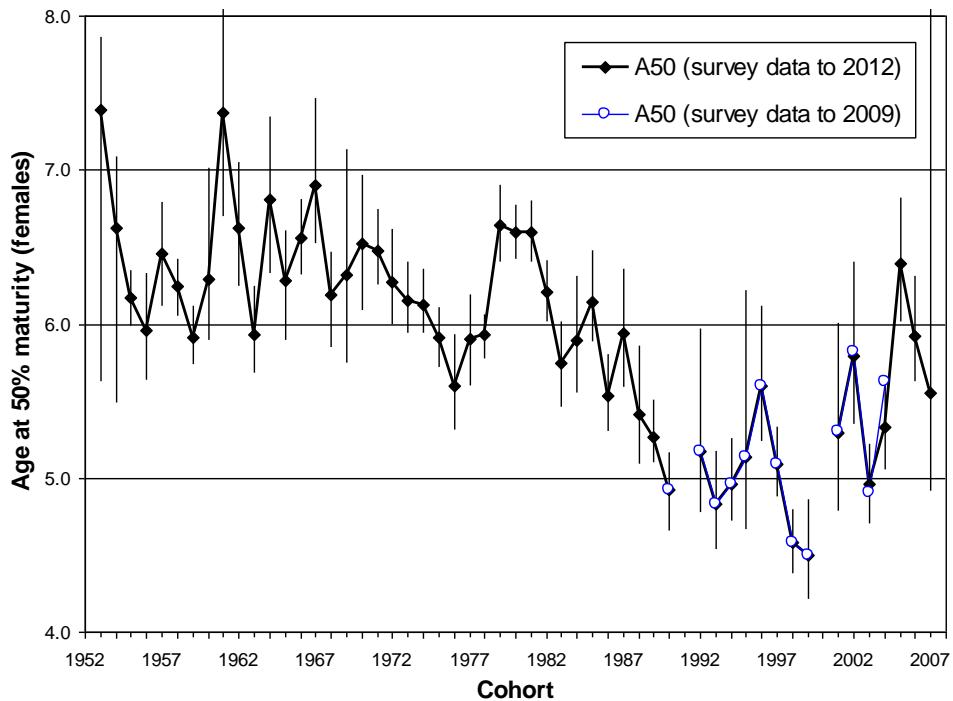

Fig. 10 - Age at 50% maturity by cohort (1953-2007, excluding 1991 and 2000) for female cod sampled during DFO spring research vessel bottom-trawl surveys of NAFO Divs. 3NO. Error bars are 95% fiducial limits.

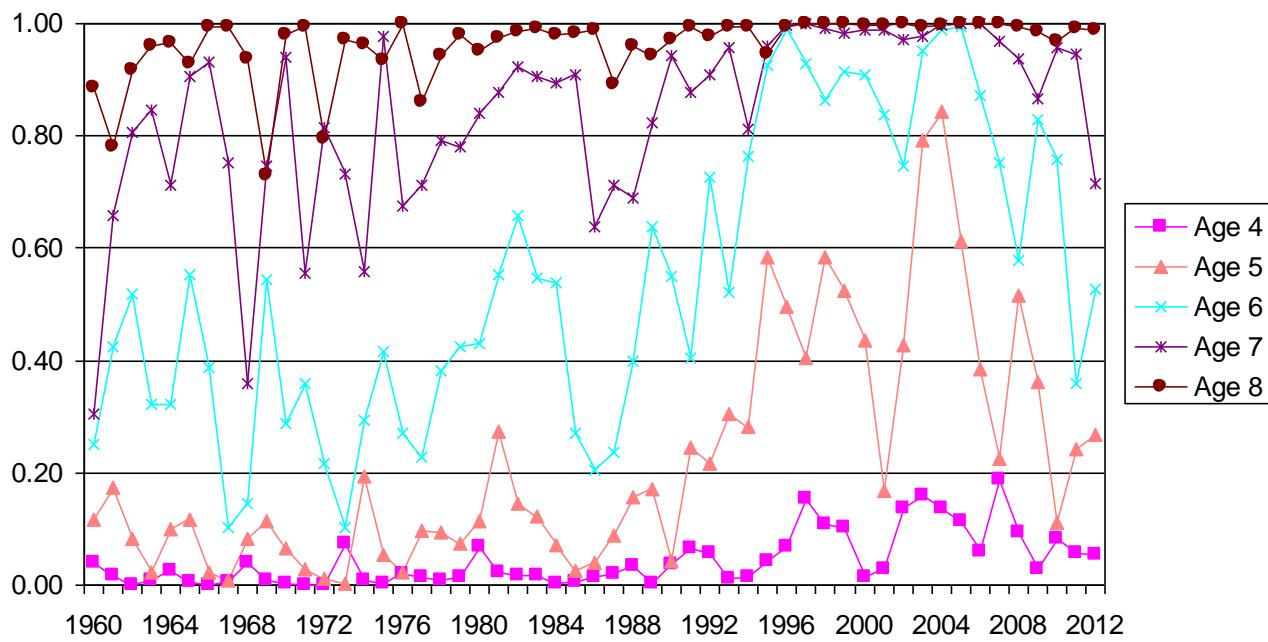

Fig. 11. Estimated proportions mature at ages 4-8 for female cod sampled during Canadian research vessel bottom-trawl surveys in NAFO Divs 3NO. Model fitted by cohort to observed proportions mature at age from 1975-2012.

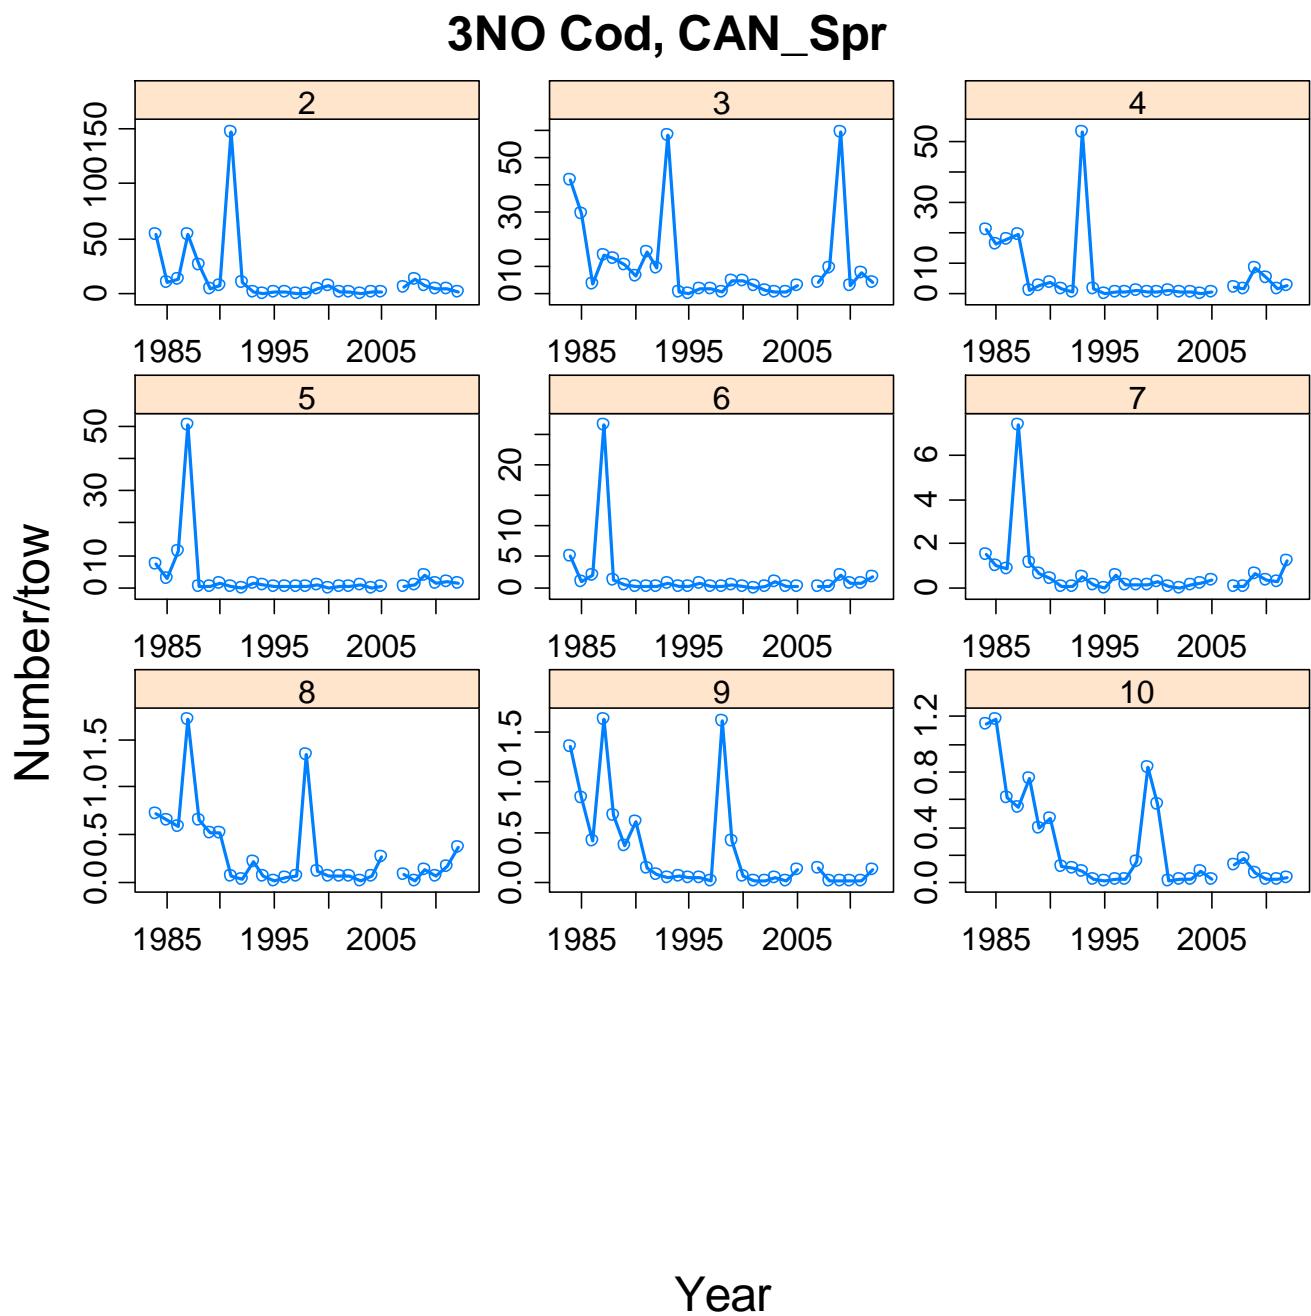

Fig. 12a. Age by age disaggregated plots of mean number per tow from Canadian SPRING surveys from 1984-2012.

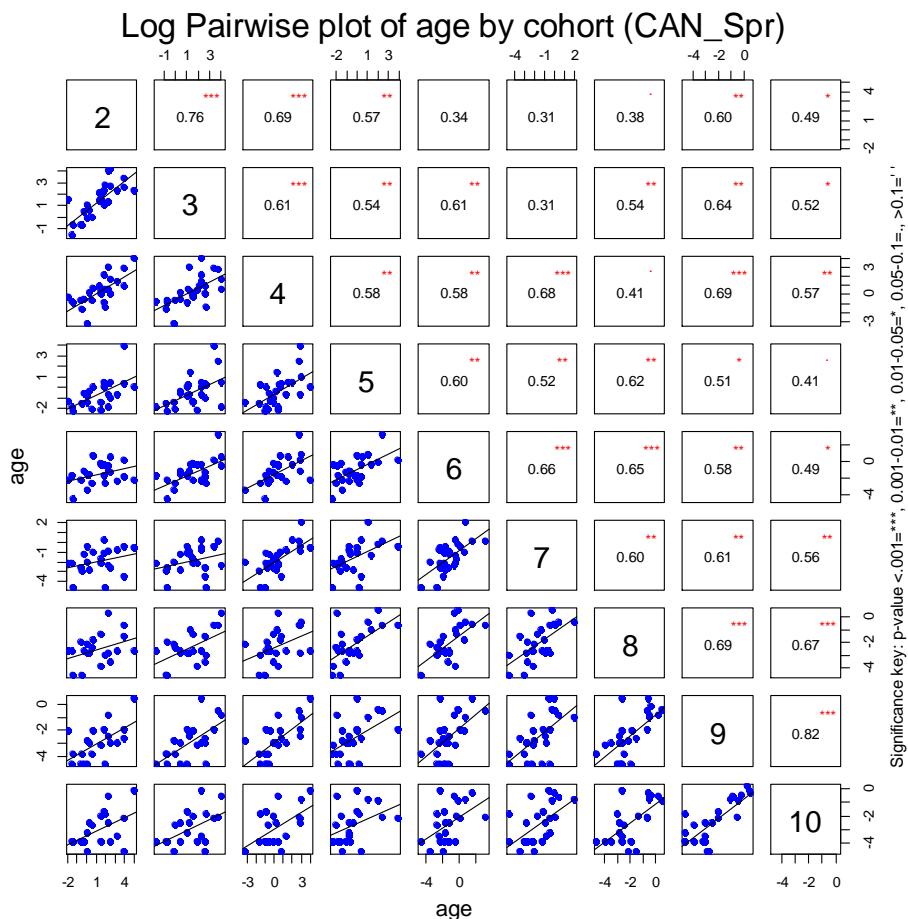

Fig. 12b. Pair-wise scatter plot of age-disaggregated survey data (log-scale) from Canadian SPRING surveys in Divs. 3NO (1984-2012). Data points in the panels below the numbered diagonal compare the logarithm of survey data at different ages for a common cohort. The solid line in each panel is the linear least squares regression line with the correlation coefficient provided in the corresponding diagonal panel (p-values significantly different than 0 noted with asterisk (see key on right side of diagram)).

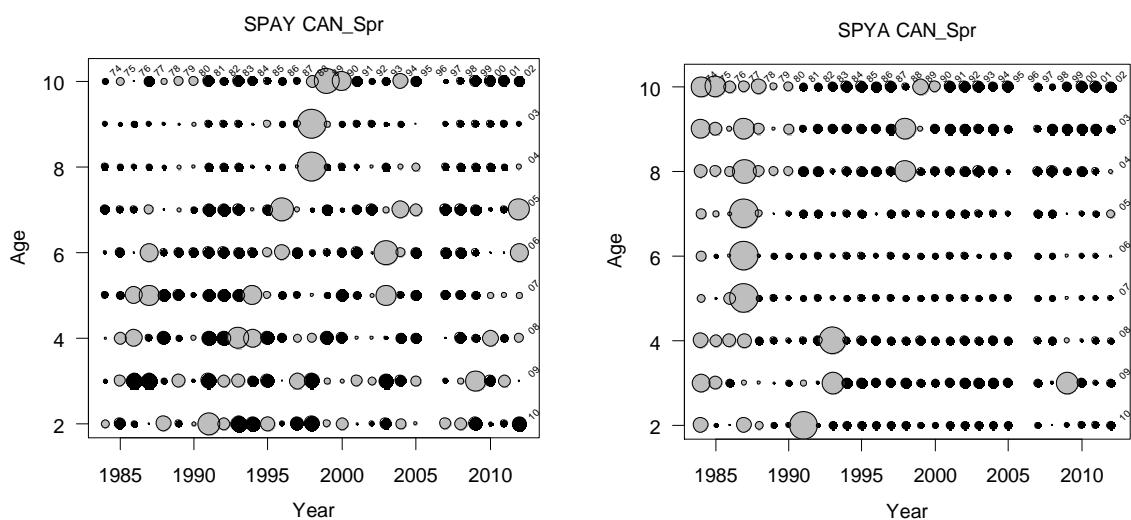

Fig. 12c. Cohort consistency plots for the Canadian Spring surveys in 3NO (1984-2012). Age disaggregated mean number per tow were converted to proportions within an age (left panel, SPAY) or within a year (right panel, SPYA). For each survey-age, the survey data are standardized to have a mean of 0 and a variance of 1. Symbol sizes are scaled and values greater than average are shown as grey circles, average values are shown as small dots, and less than average values are shown as black circles.

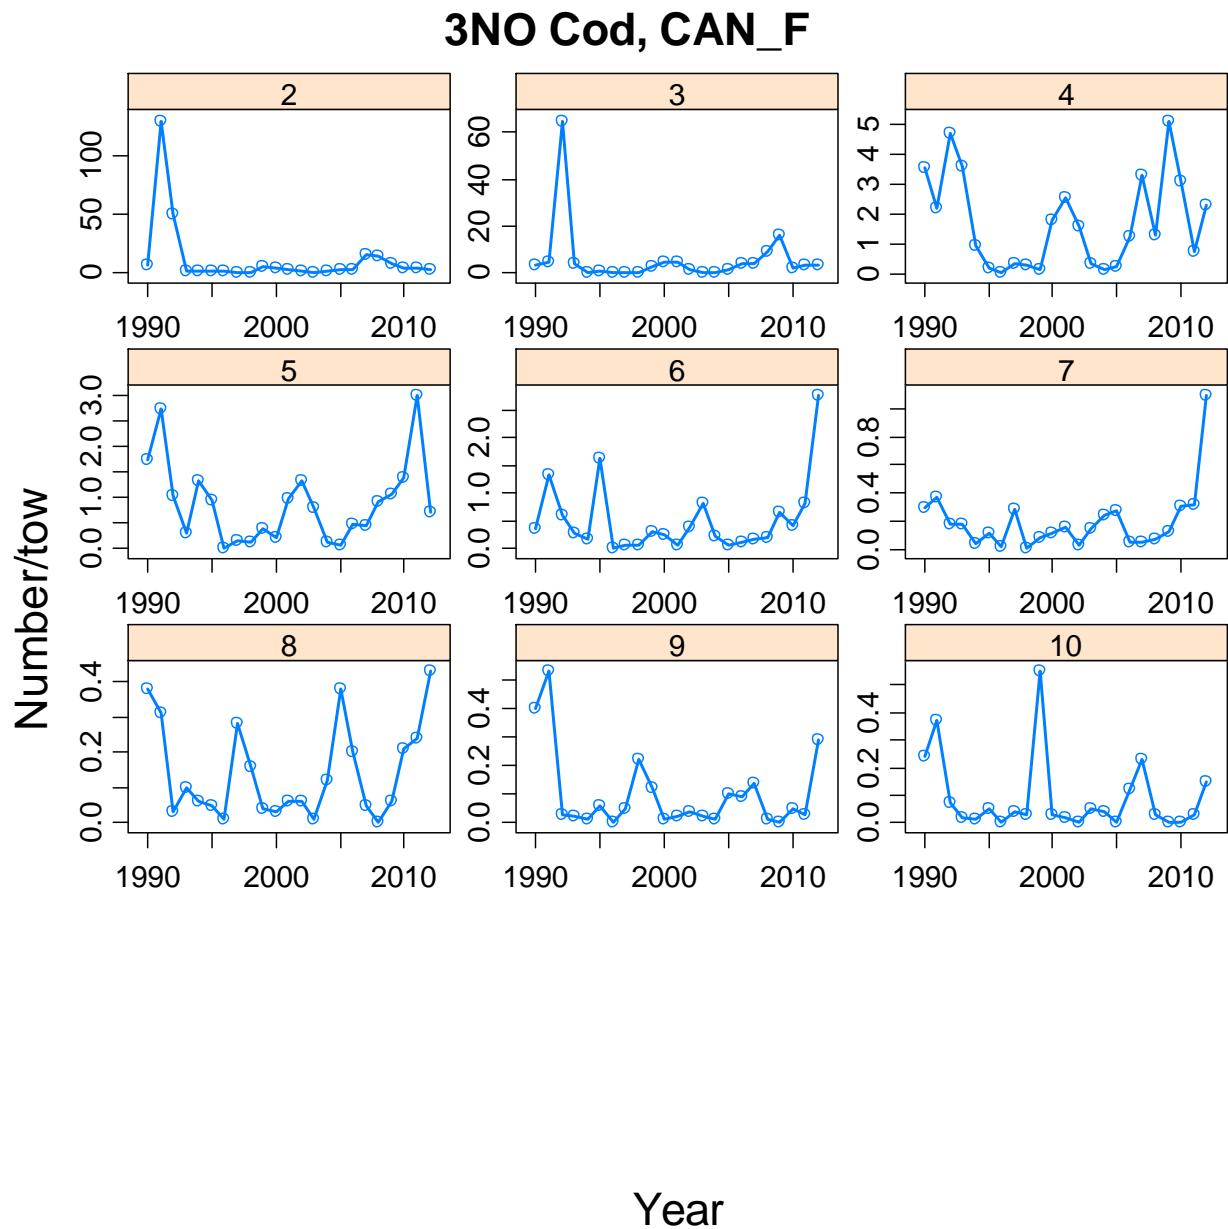

Fig. 13a. Age by age disaggregated plots of mean number per tow from Canadian AUTUMN surveys from 1984-2012.

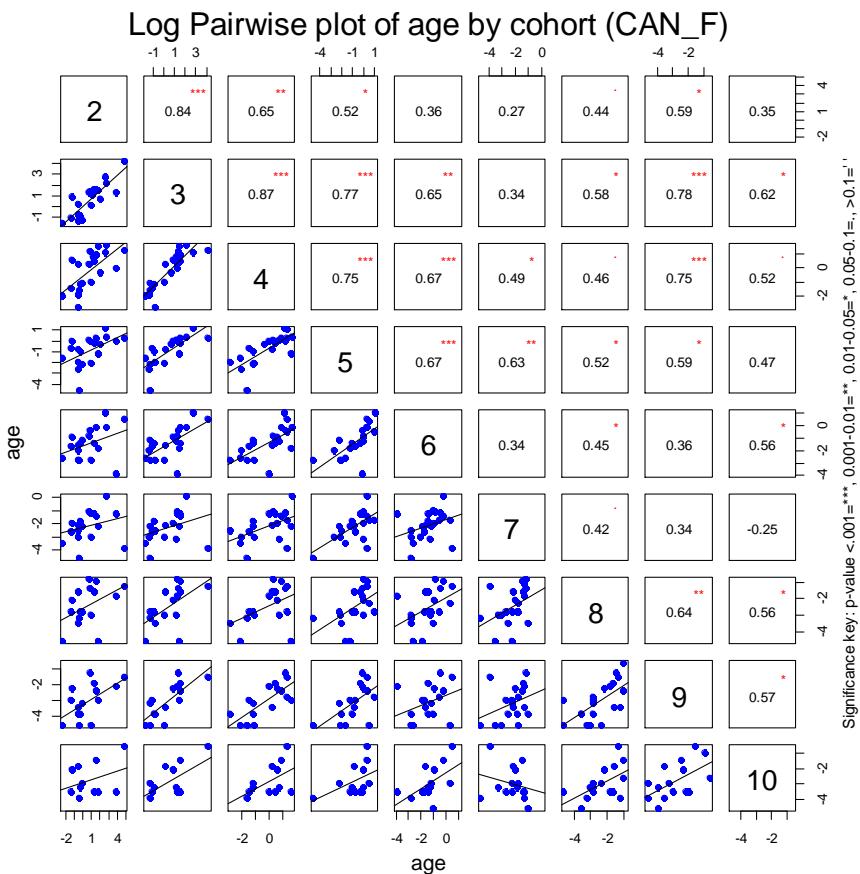

Fig. 13b. Pair-wise scatter plot of age-disaggregated survey data (log-scale) from Canadian AUTUMN surveys in Divs. 3NO (1990-2009). Data points in the panels below the numbered diagonal compare the logarithm of survey data at different ages for a common cohort. The solid line in each panel is the linear least squares regression line with the correlation coefficient provided in the corresponding diagonal panel (p-values significantly different than 0 noted with asterisk (see key on right side of diagram).

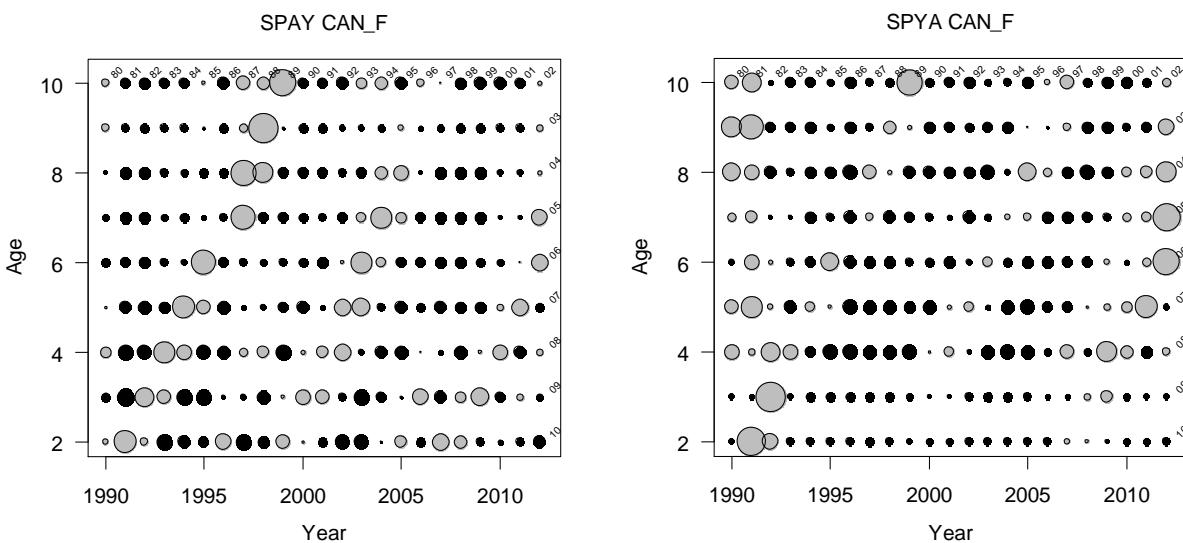

Fig. 13c. Cohort consistency plots for the Canadian AUTUMN surveys in 3NO (1990-2012). Age disaggregated mean number per tow were converted to proportions within an age (left panel, SPAY) or within a year (right panel, SPYA). For each survey-age, the survey data are standardized to have a mean of 0 and a variance of 1. Symbol sizes are scaled and values greater than average are shown as grey circles, average values are shown as small dots, and less than average values are shown as black circles.

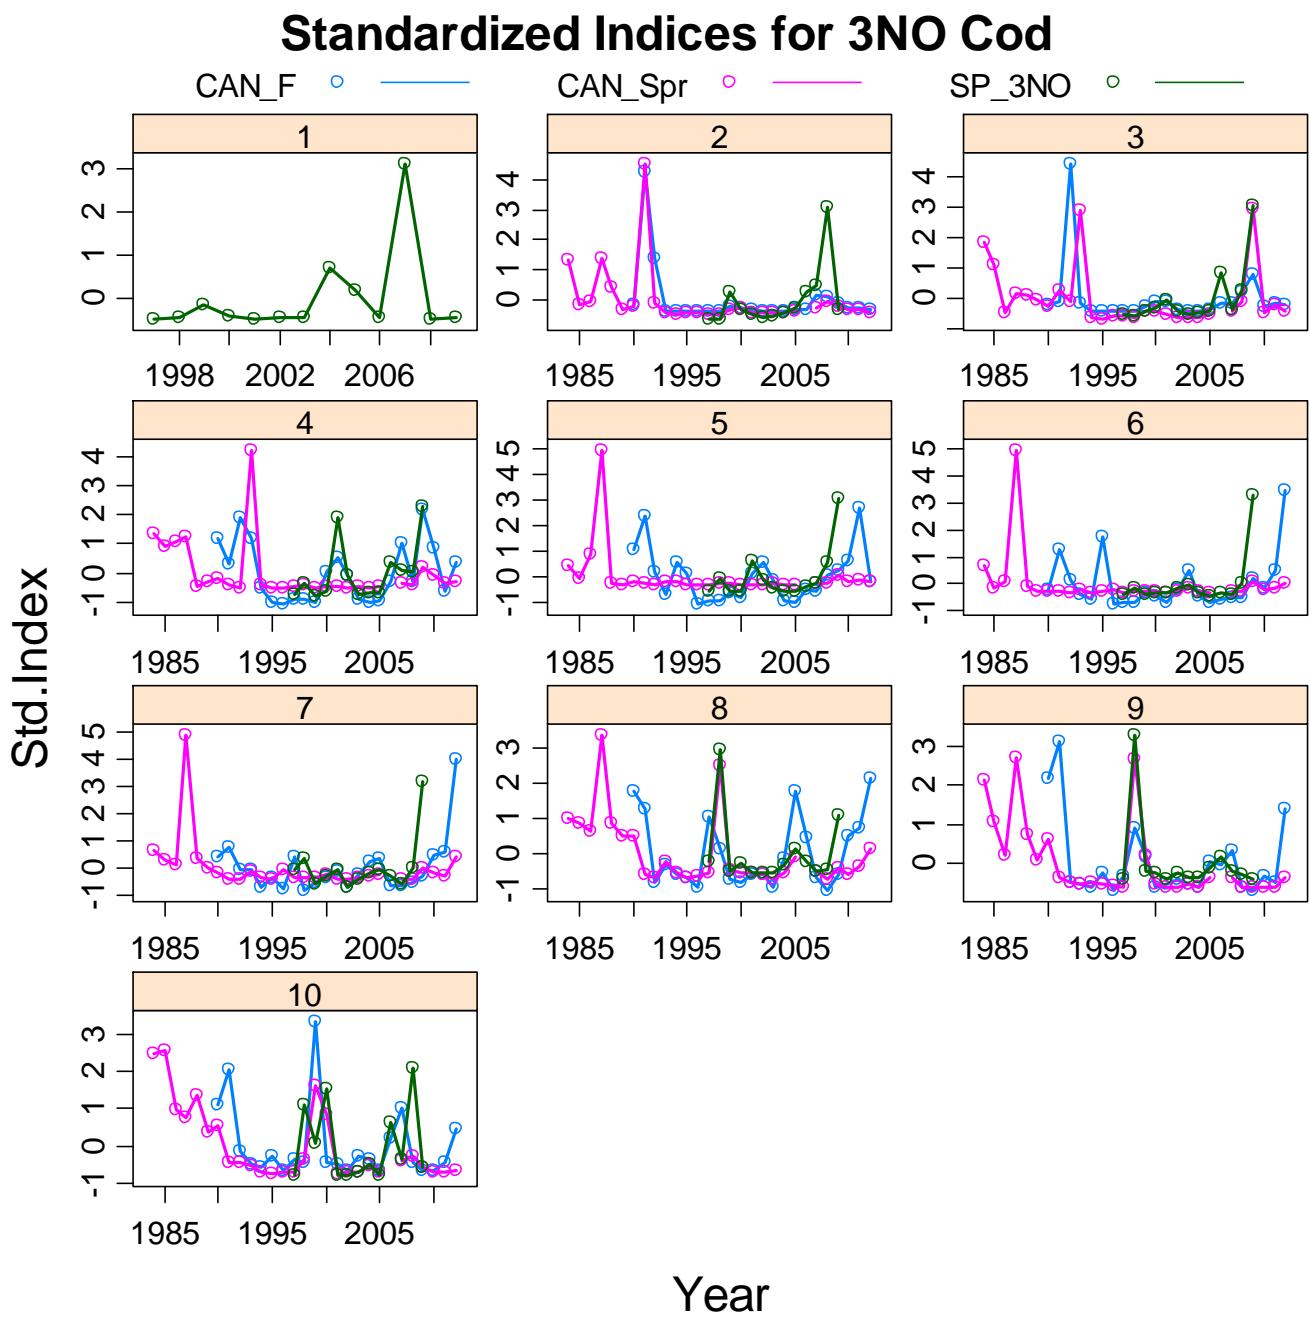

Fig. 14. Cohort consistency plots for survey indices for 3NO cod (Canadian SPRING, Canadian Autumn and Spanish 3NO). Plotted are standardized indices at age.

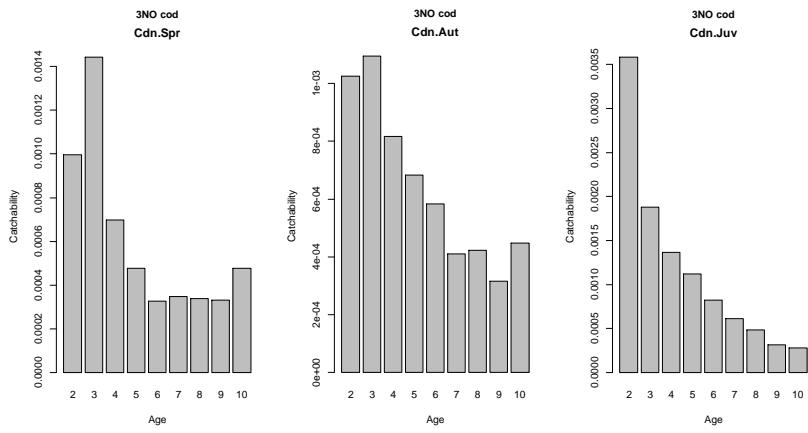

Fig. 15. Estimated catchabilities from ADAPT.

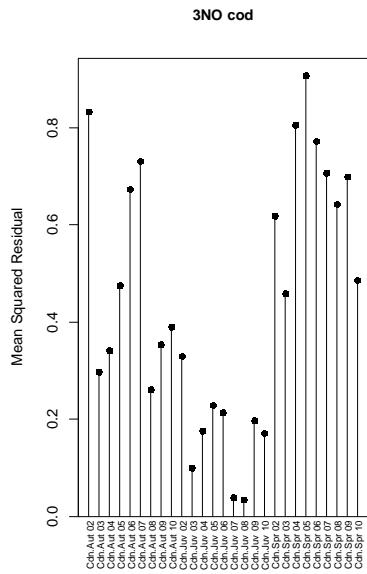

Fig. 16. Mean squared residual at age for each index in the ADAPT.

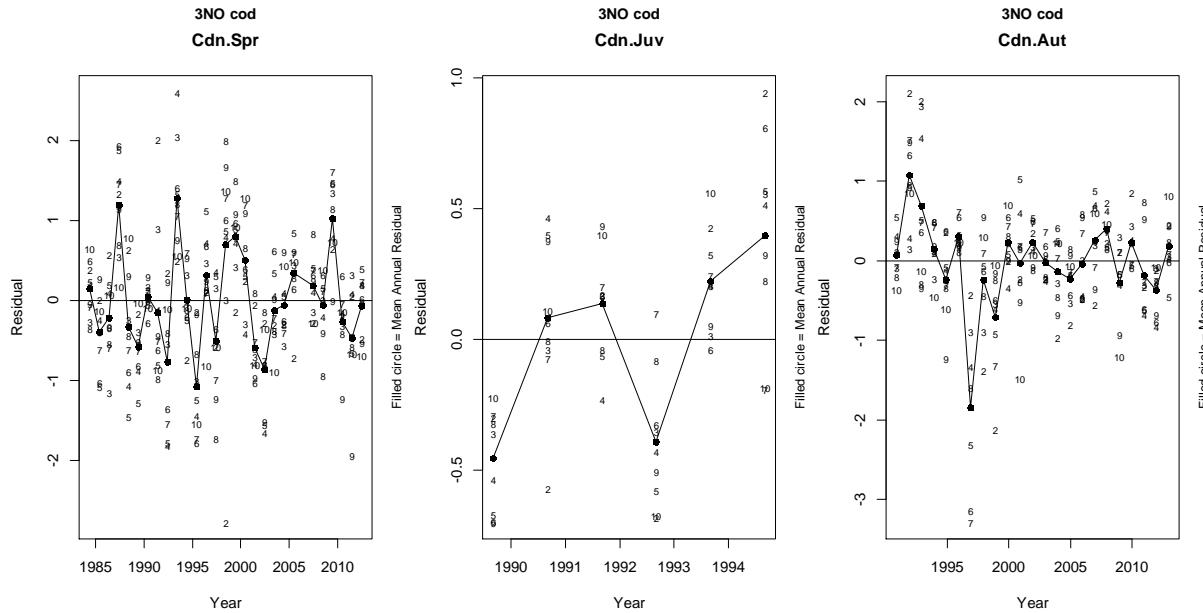

Fig. 17. Residuals at age for each index in the ADAPT.

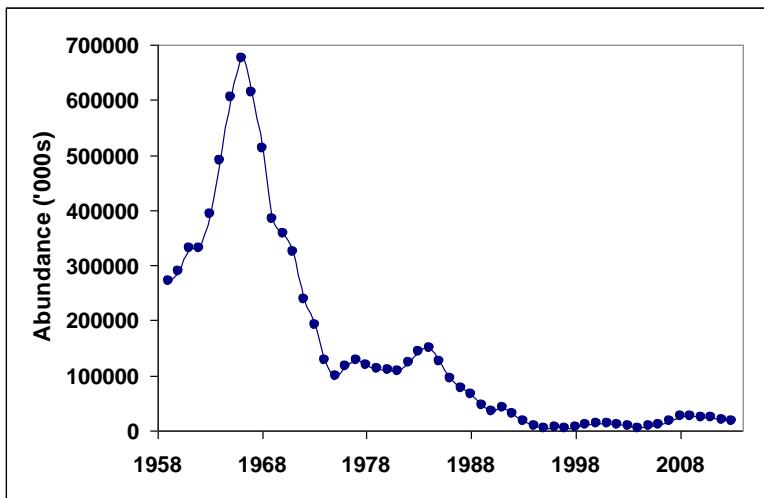

Fig. 18. Bias corrected Population Abundance for cod in Divs. 3NO as estimated from ADAPT

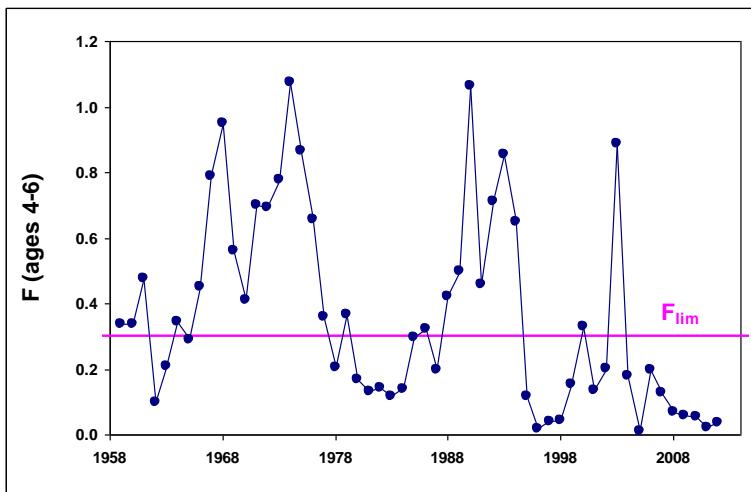

Fig. 19. Fishing Mortality for cod in Div. 3NO as estimated from ADAPT.

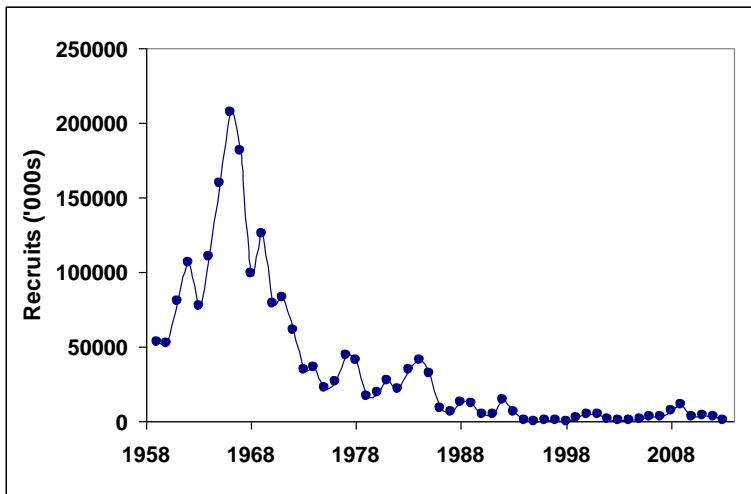

Fig. 20. Age 3 recruits for cod in Div. 3NO as estimated from ADAPT.

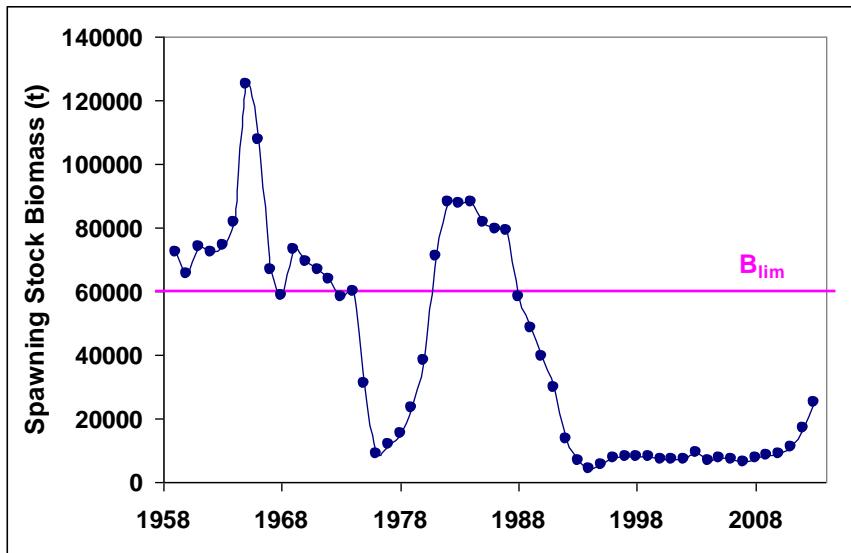

Fig. 21. Spawner biomass for cod in Div. 3NO as estimated from ADAPT.

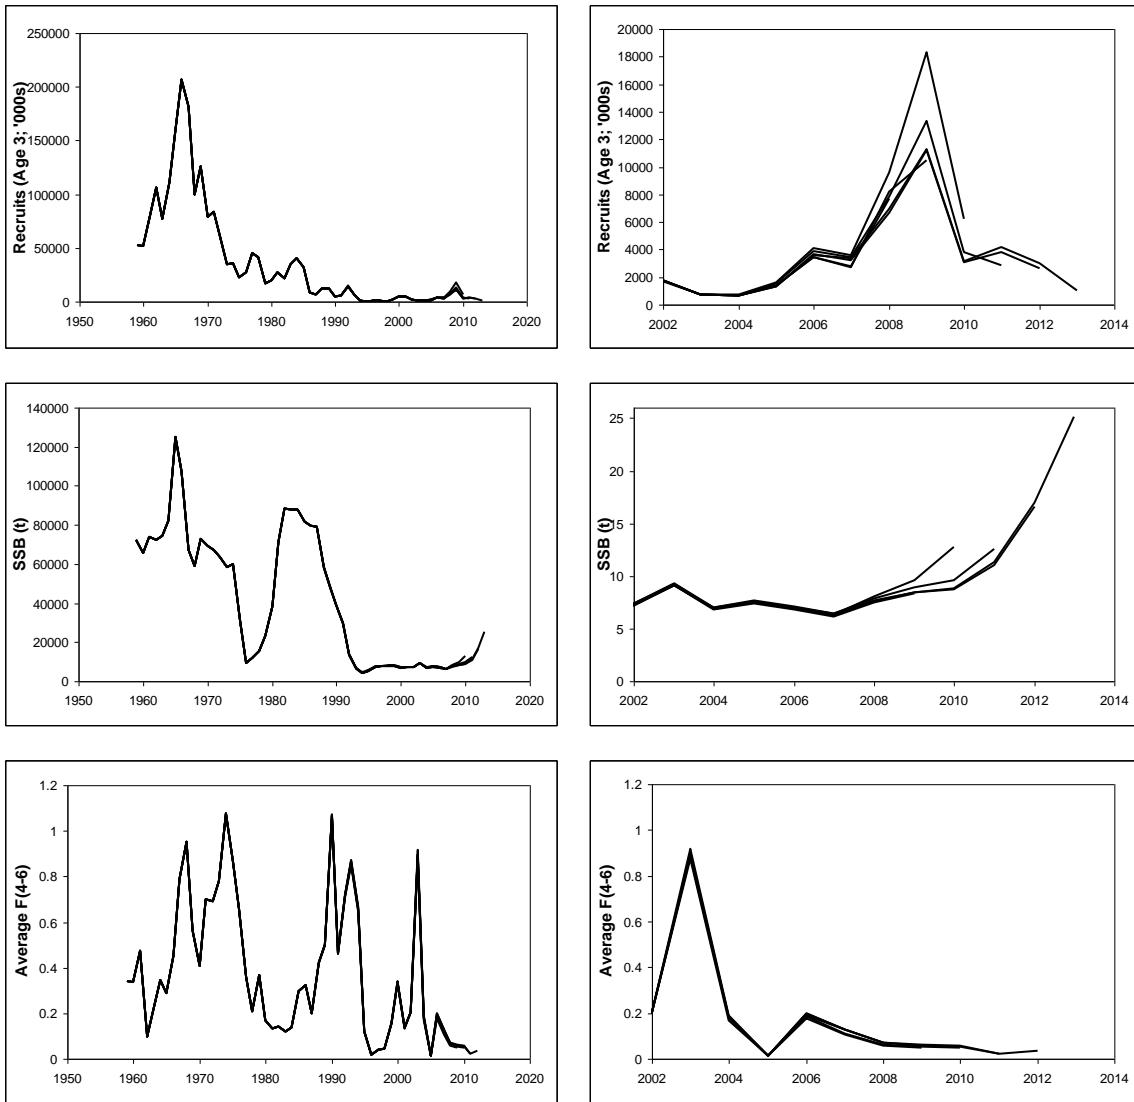

Fig. 22. Retrospective estimates of Age 3 recruits (left panel on log scale), spawner biomass and fishing mortality ($F_{\bar{4}-6}$) for cod in Div. 3NO. Right panels indicate the estimates over a shorter timeframe to emphasize recent trends.

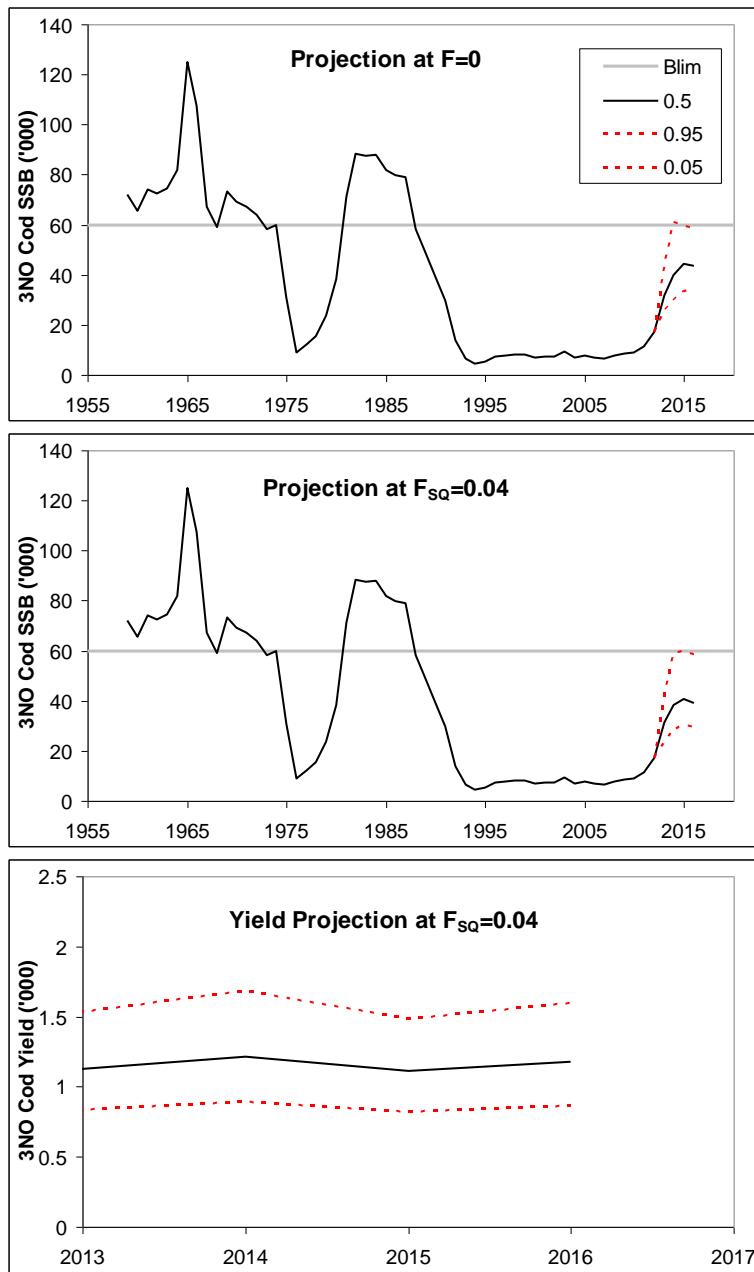

Fig. 23. Stochastic projections of SSB for $F=0$ and SSB and yield for $F_{SQ}=0.04$.
