SCIENTIFIC COUNCIL MEETING – SEPTEMBER 2013

Northern Shrimp (Pandalus borealis) on Flemish Cap Surveys 2013

by

J. M. Casas

¹Instituto Español de Oceanografía, Apdo. 1552, 36200 Vigo, Spain e-mail:<u>mikel.casas@vi.ieo.es</u>

Abstract

A stratified random bottom trawl survey on Flemish Cap was carried out from June 26th to July 23th 2013. The area surveyed was extended up to depths of 800 fathoms (1450 meters) following the same procedures as in previous years. This year a total of 181 valid hauls were made by the vessel *R/V Vizconde de Eza* with the usual survey gear (Lofoten), 120 up to 730 meters depth. The surveyed area has properly prospected the 32 strata planned. The general indexes for shrimp were estimated taken into account the traditional swept area (strata 1-19, up to depths of 730 m.) and the total area surveyed (strata 1-34, up to depths of 1450 m.). As the last years the strata 26 and 27sited in the southeast of the bank with depths from 600 to 800 fathoms (1100-1400 m.) will not be surveyed due to the presence in the bottoms of great quantities of mud and sponges.

The results concerning shrimp are presented and compared to those from previous years of the same series. The biomass and abundance in 2013 decreased since 2012 (20 % and 21% respectively), and again they were the lowest values recorded in the EU survey series. The youngest specimens (age 1) were present in the catch but at very low level, and they were weakly presents in the small mesh size bag attached to the cod-end of the main gear, suggesting the absence of any strong year classes since 2003. Unlike other years, the decline of shrimp biomass in Flemish Cap in 2013 was not associated with the increase of the cod stock biomass.

Introduction

The aim of this paper is to show the results about shrimp obtained in the summer bottom trawl surveys in Flemish Cap (NAFO Regulatory Area of Div. 3M) in 2013. Also they are compared with that obtained between years 2003-2012 by the R/V *Vizconde de Eza*, and with the transformed series previous to 2003 obtained by the R/V *Cornide de Saavedra*.

Serial No. N6221

Material and Methods

Survey design and gear used

The surveys on Flemish Cap (NAFO Regulatory Area of Div. 3M) was initiated by UE in 1988 and carried out in summer (June-July), on board the Spanish Research vessel R/V *Cornide de Saavedra* until 2002 year. Since 2003, the R/V *Cornide de Saavedra* was replaced by the R/V *Vizconde de Eza*. The gear used was a bottom trawl net type Lofoten during the whole of period.

In 2013 the survey was carried out from June 26th to July 23th. As previous years, the area prospected in Flemish Cap was spread up to 1450 meters. In 2013 as in previous years the strata 26 and 27 in the southeast of the Flemish Cap with depths between 1095 and 1450 m. were not prospected due to the presence in the bottoms of great quantities of mud and sponges. The haul number carried out in the traditional 19 strata with depths minor than 740 m. was of 120. The area with depths higher than 740 m. was sampled by means of 61 additional hauls proportionally distributed in the new 13 strata.

The bottom trawl surveys followed the same procedures as in previous years. The specifications about the main technical data of the survey are described in Table 1.

Sampling

Wherever it was possible samples of approximately 1.5 kilogram shrimp were taken in each tow where this species was present for length frequency determination. Also, some samples were frozen for length-weight analysis in the laboratory.

Shrimps were separated into males and females according to the endopod of the first pleopod (Rasmussen, 1953). Individuals changing sex phase, according to this criterion, were included as females. Females were further separated as primiparous (first time spawners) and multiparous (spawned previously) based on the condition of the external spines (McCrary, 1971). Ovigerous females were considered as a group and were not included with multiparous females.

Oblique carapace length (CL), the distance from the base of the eye to the posterior dorsal edge of the carapace (Shumway *et al.*, 1985), was measured to the lower 0.5 mm length-classes. Sampling length data were used to obtain an estimate of population length distributions in the whole area and to compare it with the estimates of the other years.

Sex reversal (L_{50F}) and length at maturity (L_{50MF})

In order to analyze changes in the length at maturity, from each length class the proportion (pi) of mature females against all specimens was calculated. The method used to estimate the maturity ogive and the length where the 50% of the specimens are mature females (L_{50MF}) was based on fitting of the sigmoid, so-called logistic curve.

The equation used was

$$Y = 1/(1 + e^{-(a+bx)}).$$

With a y b being the intercept and slope respectively of the regression Ln (pi/1-pi) on length class.

The logistic curve was fitted each year using a non-linear method to estimate the parameters by iteratively minimizing the sum of squares of the deviations between observed and predicted proportions where the mature females were presents.

In the same way the sex ratio by length classes were estimated to obtain the length at sex change where 50% of the specimens are females (L_{50F}).

Age composition and MIX program

As previous years the length frequency distribution by sex group were analysed by MIX program and the proportion, mean lengths and standard deviations of the mean length (sigma) are calculated for each age component and sex group. When the modal components overlap and obscure one another, was necessary to reduce the number of parameters estimated in order to get the best and reasonable adjust. We have constrained sigma very often fixing the coefficient of variation (CV) at 0.045 or keeping it constant.

After getting the proportions and mean lengths for every age/sex group the results were used to calculate the total number of individuals in every age/sex group according to the biomass estimate. This was done by transforming the CL to weight using the weight length relationship estimated each year during the survey. So, the mean lengths were converted to mean weights to calculate the number of males, primiparous females and multiparous females (Skúladóttir and Diaz, 2001).

Small mesh size bag on the cod-end

Knowing that mean size of shrimp coincides with the selection range of the 35 mm mesh currently used, a bag with 10 mm mesh size was attached as last years to the cod-end of the Lofoten gear, just in a position where escapement is believed to be the highest. The base of the bag was a square of 36 cm in each side. The whole shrimp caught in the juvenile bag was weighted and measured.

Results

Biomass

This year a total of 181 valid bottom trawls were completed with Lofoten trawl gear in Flemish Cap survey, 120 of them were carried out in the traditional strata prospected from 1988 with depths up to 740 m. (400 fth.) (Fig. 1).

Total shrimp biomass, estimated by swept area method and mean catch per tow from 1988 to 2013 are presented in Table 2. The values presented from 1988 to 2002 year are those resultants of the Warren's transformation of the lengths distribution obtained by the R/V *Cornide Saavedra* and the length-weight relationship estimated every year (Casas *et al.* 2005).

The increasing of biomass since 1988 to 1992, coincided with a period of time where there was not a directed fishery to shrimp and the cod stock began to decline. With the beginning of the shrimp fishery in 1993 the biomass declined up to 1997. After that the stock recovered reasonably well although with high annual variability (historical maximums in 2002 and 2005 were followed by years with lower biomass but at a relative high level). In 2009 the biomass decreased sharply with values close to the lowest of the historical series. In 2010 despite of the biomass increase about 77% compared to 2009 this was still among the lowest in the total of the historical series. From 2011 the total and female biomass decreased successively and were recorded the lowest values in the historical series showing the worsening and depletion state of the shrimp stock (Table 2). The total and female biomasses estimated in 2013 were 844 and 691 t. respectively (Fig. 2).

Biomass estimated by depth strata from 1988 to 2013 is shown in Table 3. The presence of shrimp in shallowest strata, with depths less than 140 fathoms (257 m), was scarce in the first years (1988-1995). However, since 1996, a noticeable amount of shrimp occurred in these strata and the estimated biomass increased up to 2002 and 2003 years where the 36% and 41% respectively of the total biomass were estimated in depths lesser than 140 fathoms. After these years the biomass estimated in these depths declined each year and from 2008 to 2011 they were residual (in 2011 the 0.1% of the total biomass). In 2012 the biomass in these strata increased strongly (20%) mainly due to the presence of shrimp in only one tow in the shallowest strata (70-80 fth.). In the present year 2013 the biomass was again among the lowest recorded (2%). According to this, the catch distributions observed during the 2013 survey (Fig. 3) showed a patched distribution around the central area of the bank but with greater presence in medium depth strata (201-300 fth.).

Adult stock, female biomass

Total biomass estimates by the series of bottom trawl surveys on Flemish Cap from 1988 to 2013 (Table 2 and Fig. 2) are quite variable, due to the predominant sizes of the shrimp are in the selection range of the cod-end mesh size used (35 mm), so the biomass estimations are clearly affected by small changes in cod-end mesh size between years. To solve this problem it was proposed to use the shrimp bigger than 20 mm CL (Table 2). The biomass for shrimp bigger than 20 mm CL tried to be an index of the adult biomass not affected by differences in the cod-end mesh size used. The 20 mm CL was chosen because it is approximately the limit between 3 and 4 years old shrimp in this season (Garabana, 1999). The biomass estimated for shrimp bigger than 20 mm. in 2013 was 714 t.

The use of female biomass estimate is also an index not affected by small changes in mesh size, and it is the one used by the NAFO Scientific Council, so it was also included in Table 2. In 2013 the estimated female biomass (691t.) was about 13% lower than 2012. Both indices (females and shrimp bigger than 20mm. biomass) were the lowest values in the EU survey series.

The standard gear used in the surveys was a Lofoten with a cod-end mesh size of 35 mm with the exception of the 1994 and 1998 surveys when a 40 mm and 25 mm cod-end mesh size were used respectively. Consequently, the biomass index in 1994 is supposed to be underestimated and that of 1998 could have been overestimated by a factor of two (del Río, 1998).

In the figure 2 the adult biomass estimates are compared with the total biomass and female biomass along the series. Differences between these quantities in every year correspond to the greater or smaller catch of young shrimp. These differences are showed as percentage of the total biomass in the figure 4 and table 5. Although the smaller size-classes are more directly affected by small changes in the cod-end mesh size the differences between the total biomass (>20 mm.) showed an increasing trend in the period 1988-2005 from 6% in the beginning of the series to 56% in 2005. Since 2006 the increasing trend changes and difference between total biomass and adult biomass decreases to levels prior 1997 year. The high value founded in 1998 (60%) was due to the lesser mesh size of the linner codend used (25 mm.), and not comparable conclusions can be thrown.

The decrease in the length at sex change is a general trend since 1992 to 2006 (Fig.5a.). After that the length at sex change increased year after year up to 2010 (20 mm.). Since 2011 the length at sex change remains stable at 2010 levels. The length at maturity (L_{50MF}) (Fig. 5b), showed a similar and decreasing trend up to 2006. After that year the L_{50MF} shows an increasing trend reaching in 2013 25.2 mm. next to 1993-1997 levels.

Length frequencies

The length frequencies and percentages by sex for 2013 are shown in the Table 4. These length frequencies are split into males, primiparous females, multiparous females and ovigerous. The table 5 shows also the male percentage in number in the historical series from 1995 to present. From this table it can be observed the increase of male percentage, getting in 2005 the highest value in the historical series (75%), with the exception of 1998 (which can not be compared as it was before said). From 2006 the male percentage decreased showing in 2013 the lowest value recorded in the historical series of the EU surveys (25.3 %).

The Fig. 6 shows the length distribution by sex on EU Flemish cap 2004-2013 surveys. In 2004 year the youngest modal group (age 1) was well represented with a modal length about 9-10 mm. With the exception of 1998, where a lesser mesh size was used in the survey (25 mm.), the most important modal size in the historical series occurred in 2002 and 2005 around 18 and 16.5 mm CL respectively. Since 2006 the importance of the youngest individuals decreased markedly. Since 2009 the lack of strong year classes and the successive bad recruitments in the last years have caused a drastic fall in the frequencies of practically all the length groups compared with those obtained in previous years. In 2013 the absence of strong year classes persisted and the decrease of biomass was mainly caused by the depletion of both sexes.

The shrimp length distribution estimated in the surveys since 1988 with the Lofoten gear did not record adequately the small size groups in the beginning of the historical series. Since 1996 the age 2 was present in the catches in a significant way and the introduction of the new vessel in 2003 improved the catchability of this age; mainly due to the technological advances in maintaining more stable the performance of the fishing gear.

Since 2001 the routine use of a small mesh size bag attached to the cod-end to collect a portion of the small size shrimp escaping through the meshes was a common alternative. Total catch and length frequencies obtained with the small mesh size bag in 2013 survey were very low and they are presented in Table 6. The estimated biomass was 1.1 t. and the length distribution showed three modes at 12, 16 and 19 mm. CL, corresponding to age-classes 1-3 (Table 7 and Fig. 7).

Length-weight relationship

Length-weight relationships by sex group in year 2013 are illustrated in Fig. 8. Length-weight equations by sex group for this period were:

| For males: | $W = 0.0011 \times CL^{2.834}$ | (N= | 1236, | $r^2 = 0.96$) |
|--------------------------|---------------------------------|-----|-------|----------------|
| For primiparous females: | $W = 0.0020 \times CL^{2.6158}$ | (N= | 2528, | $r^2 = 0.91$) |
| For multiparous females: | $W = 0.0016 \times CL^{2.2693}$ | | 1428, | $r^2 = 0.91$) |
| All sexes combined: | $W = 0.0015 \times CL^{2.7089}$ | (N= | 5192, | $r^2 = 0.96$) |

Where W is weight in g and CL is the oblique carapace length in mm.

Age structure

The Table 7 and the Figures 7 y 9 show one preliminary and visual interpretation of shrimp modal groups and ages from the length distribution obtained by the gear Lofoten and juvenile bag used in 2013.

Age assessment was carried out using the MIX software from the shrimp length distributions estimated every year in the survey series. The results of the modal analysis for annual surveys 2013 is shown in Table 8. The proportions within each sex group are listed as well as mean lengths and standard deviation (sigma) by age-classes.

The results of Table 8 were then used to calculate the mean length, abundance and biomass at age Tables 9, 10 and 11. The modal analysis in 2013 identified six age groups (ages 1 to 6). The mean lengths by age decreased at the biggest age groups to level 2008-2009 level and the age at sex change was similar to the last year (3 years old with 19.9 mm.C.L.). The decline of biomass in 2013 was as in 2011 due to the general decreasing in all age groups.

At the beginning of the series (1988-1995) the youngest shrimp were considered to be three year olds with lengths between 15.4 and 18.2 mm. Since 1996 shrimps with two years old have been present and the lengths ranged between 12.5 to 15.9 mm. The shrimps with one year old appeared at first time in 1998 and were present up to 2003 with lengths around of 10 mm. In spite of the variability of the length by age along the years, from the beginning of the series to 2007 it can be observed a decreasing trend in the mean length of the main age groups (Fig. 10). This trend was mainly pronounced since 2004, due to the presence in these years of the strong 2002 year class with mean lengths at age below average. Since 2007 this trend changed and the mean lengths at age increase significantly up to 2010. Since then the mean lengths changes without a clear trend at different ages.

Some strong year-classes may be followed according the abundance by age groups from 1988 to 2006 (Table 10) if the assignation of the age is right. The 1986 year-class stand out in the beginning of historical series with 4, 5 and 6 years olds in the years 1990, 1991 and 1992. The individuals with 4 year olds were also especially abundant in the years 1999-2002 indicating the strong of year-classes 1995, 1996, 1997 and 1998. The 1999 year-class stand out especially judging by the high number of 3 and 6 year olds in 2002 and 2005 years respectively. In these two years both the biomass and the abundance reached out the highest values in the series, especially in 2005 where the strong 2002 year class with 3 years old was also present. From 2004 to present the virtual absence of age group 1 in the catches and very low values for the ages 2 and 3 show the weakness of the 2003 -2012 year classes.

Considering the abundance at age 2 as indicator of recruitment, the number of shrimp of two years old in the survey and from juvenile bag (Table 8) were estimated and the index average-weighed (Fig. 11 and Table 12). Since 2005, the survey indices from Lofoten gear showed lower values than in previous years indicating the sequence in recent years of weak year classes. A similar trend can be observed from juvenile bag's indexes. In 2013 survey this decreasing trend continues and confirms the weakness of the last recruitments.
