SCIENTIFIC COUNCIL MEETING – JUNE 2017

An analyses of logbooks of Greenland Halibut Stock Component in NAFO Division 1A Inshore.

by

Frank Rigét and Rasmus Nygaard

Greenland Institute of Natural Resources, P.O. Box 570, 3900 Nuuk, Greenland

Abstract

This paper presents an analyses of logbooks data of the commercial gillnet and longline fishery of Greenland halibut in NAFO Division 1A inshore. The majority of the inshore fishery is concentrated in the Disko Bay and the districts surrounding Uummannaq and Upernivik. Logbooks have been mandatory for vessels larger than 30'ft since 2008 and constitute the basic of the estimation of a gillnet and longline standardized CPUE-series for the Disko Bay, Uumannaq and Upernivik districts.

Introduction

Greenland halibut can be found in all waters around Greenland both offshore and inshore but the highest concentrations has always been found in NAFO division 1A inshore. The stock is considered to be recruited from the stock in the Davis Strait, but the adults appear resident in the fjords and are isolated from the offshore spawning stock (Riget and Boje, 1989). As a result, the inshore component probably does not contribute significantly to the spawning stock in the Davis Strait (Boje, 1994). In samples from Disko Bay <10% of females in the reproductive age, were mature during the assumed peak spawning period in spring (Simonsen and Gundersen 2005) and only sporadic spawning has been observed in the inshore area (Jørgensen and Boje, 1994). The inshore component is assumed not to be self-sustainable, but dependent on recruits and immigration from the offshore area (Bech, 1995).

Description of the fishery

Longline fishery constitutes the majority of the total landings. In the late 1990s, the first regulations limiting areas open to gillnet fishery were introduced, limiting gillnet fishery to the winter season. Competence to regulate seasons and areas open to gillnet fishery, was transferred to municipalities in 2004, and areas open to gillnet fishery has expanded since then. The gillnet fishery is regulated by a minimum mesh-size of 110 mm (half meshes) although increased illegal use of cod gillnets (80mm) used to target Greenland halibut has been observed since 2008. Licences requirements were introduced in 1998 and in 2008 TAC and quota regulations were introduced for the inshore fishery.

The fishery in the Disko bay has always been highly concentrated around the bank just south of Ilulissat and typically more than one third of the Disko Bay catches are from small area (see SCR Doc.17/041). Other important fishing grounds in the Disko Bay is the deep Kangia ice fjord (>900m) and the northern part of the Disko Day concentrated around the settlements Saqqaq and Qeqertaq and the ice fjord Torsukattak east of the settlements. The fishery in Uummannaq is scattered all over the fjord near settlements (see SCR Doc.17/041). Particular in the deep South-eastern part of the fjord from Uummannaq and towards East where depths of more than 1500 meters are common and large iceberg producing glaciers are located holds the more important fishing areas. The Upernivik area consists of several large ice fjords, but the main fishing grounds are the deep Ikeq fjord (Upernivik Icefjord) and Gulteqarfik (Giesecke Icefjord) and the shallower fjords surrounding Upernivik and the settlements in the area. Use of gillnets have been prohibited in Upernivik, but derogations have been given for a fishery outside the Icefjords since 2002.

Logbook data

Logbooks have been mandatory for vessels greater than 30'ft (9,4 m) since 2008. Data on the all inshore landings are reported to the Greenland Fishery Licence Authority (GFLK). Factories receiving the catch gather information on the fishery, including effort and location on individual fishing events and send the data to GFLK on a weekly basis.

Logbook CPUE

A general linear model (GLM) with year, month and boat as factors was applied to the longline and gillnet fishery logbook data since 2008. Only longline setting with more than 200 hooks and gillnets with catches between 50 and 200 kg/gillnet were included to omit obvious outlier values. CPUE observations were log-transformed prior to the GLM analysis. Least-mean square estimates were used as standardized CPUE series.

Disko Bay

The longline logbook catch's in 2007 and 2008 were very low (Table 1) and were not included in the analyses. In most years the logbook catch constituted around 30% of the total longline catch (Table 1). The GLM model explained 22% of the total variation (Appendix 1). The mean log-CPUE and the standardised log-CPUE series was rather similar showing a decreasing trend since 2009, however the log-CPUE increased from 2015 to 2016 (Fig. 1).

The gillnet logbook catch's constituted ca. 32 to 54% of the total gillnet catch in the period from 2011 and onward (Table 1). The GLM model explained 28% of the total variation (Appendix 2). The standardised gillnet log-CPUE series has been rather stable since 2011 (Fig. 2).

Uumannaq

The longline logbook catch's constituted around 15% except in 2007 when logbooks was not mandatory, and therefore omitted in the analyses (Table 2). In most years with known separation of the total catch on longline and gillnet catch's, the logbook longline catch constituted around 15% of the total longline catch (Table 2). The GLM model explained 19% of the total variation (Appendix 3). No change in the standardised gillnet log-CPUE had occurred from 2015 to 2016 after it was at a somewhat higher level in the period from 2010 to 2014 (Fig. 3).

The gillnet logbook catch's constituted ca. 26 to 53% of the total gillnet catch in the period from 2011 to 2014 but decreased to about 7% in 2015 and 2016 (Table 2). The GLM model explained 27% of the total variation (Appendix 4). After a drop in 2012 the standardised gillnet log-CPUE had been stable (Fig. 4).

Upernivik

The longline logbook catch's constituted a lower part of the total longline catch in 2015 and 2016 (ca. 16%) compared to earlier years (Table 3). The GLM model included longline CPUE data from 2007 to 2016 and explained 25% of the total variation (Appendix 5). Since 2007 the longline CPUE has gradually decreased and were in 2015 and 2016 at the lowest level observed in the period. (Fig. 5).

The gillnet logbook catch's constituted ca. 20 to 37% of the total gillnet catch in the period from 2009 to 2014 but decreased to about 9% in 2015 and 2016 (Table 3). The GLM model explained 37% of the total variation (Appendix 6). Similar to the longline CPUE has the gillnet CPUE gradually decreased since 2009 and was in 2016 at its lowest observed in the period (Fig. 6).

Discussion

A gradual shift towards using illegal (legal for cod) 80mm gillnets (halfmesh) from mandatory 110 mm gillnets has been observed in recent years in the Disko Bay. Using more fine meshed gillnets will mean a greater overlap between the selection curve and the underlying population and therefore a more efficient gear. The use of finer meshed gillnets is a way for the fishermen to compensate for a decreasing stock (where larger fish have been lost and smaller fish remain) and maintain a higher CPUE.

Table 1. Disko bay logbooks data

Year	Total catch of Longline	No of Longline settings	Total longline logbook catch (t)	Total catch of gillnet	No of gillnet settings	Total gillnet logbook catch
2007		262				
2008		338
