NAFO/ICES *PANDALUS* ASSESSMENT GROUP – NOVEMBER 2019

Research survey results pertaining to northern shrimp (*Pandalus borealis*) in the Barents Sea and Svalbard area 2004-2019

by

Carsten Hvingel and Trude H. Thangstad
Institute of Marine Research, Framsenteret, Box 6606 Langnes, 9296 Tromsø, Norway

Abstract

The estimated mean biomass indices from the three available survey series has varied considerably since the early 1980s. with up to a five-fold difference between the lowest and highest values. The index values from the recent survey series has varied without trend for most of the period since 2004. However, it has increased substantially since a low in 2016 to reach its highest value in 2019. Since 2004 the areas of high shrimp density are gradually found further east in the Barents Sea. The changes in distribution may be associated with influx of warmer water from the south-west into the Barents Sea. This update of the survey series contains two new data points (2018 and 2019) as the 2019 assessment meeting was held later in the year after the survey annual survey had finished.

Introduction

Research bottom trawl surveys have been conducted to assess the stock status of northern shrimp, *Pandalus borealis*, in the Barents Sea. The main objectives were to obtain index values for stock biomass, abundance, recruitment and demographic composition. Recently (since 2004) the monitoring of a multitude of other ecosystem variables has been included in what now is named the joint Norwegian-Russian "Ecosystem survey" (www.hi.no).

For the assessment of Barents Sea shrimp three survey time series are available: (1) The Norwegian shrimp survey 1982-2004 (ICES, 2002, 2003, 2005), (2) The Russian shrimp survey 1984-2002 and 2005 (ICES 2006), and (3) The joint Norwegian-Russian ecosystem survey since 2004. The ecosystem survey (3) combines surveys 1 and 2, as well as several earlier 0-group and groundfish surveys.

This paper updates the information regarding shrimp from survey (3) and includes data from both Norway and Russia. The survey biomass indices derived here are used as input in the assessment model for this stock.

Methods

Survey and coverage
The joint Norwegian-Russian ecosystem survey has since 2004 been conducted annually from August to October by 4-5 research vessels simultaneously covering the entire Barents Sea. On average 360 bottom trawl hauls are taken each year from the edge of the continental shelf in the west, to Novaja Semlja in the east, from the coast of Norway and Russia in the south to the ice-edge in the north (Olsen, 2006) (Fig. 1).

In most of the covered area both in the Norwegian and Russian EEZs the survey follows a regular grid with ecosystem sampling stations approx. 30-35 nm apart (Fig. 1). In the important juvenile shrimp areas in the central Barents Sea (Hopen Deep), additional demersal trawl stations are placed at ½ the standard grid size to get a more detailed coverage of the shrimp distribution in this area. In the other high density shrimp area

in the north-west around Spitsbergen a depth-stratified survey is conducted. Here stations are placed approx. every 30-35 nm as in the other areas, but in addition a number of extra bottom trawl stations are placed at irregular intervals within this part of the survey area. The additional "shrimp stations" were reduced in numbers in 2008, and have since been omitted altogether.

Sampling trawl gear
Sampling of demersal species like shrimp within the ecosystem survey is conducted with a standard Norwegian research trawl, which is a modified Campelen 1800 shrimp trawl with rockhopper ground gear (Fig. 2). Mesh size in the cod-end is 22 mm with a 6 mm lining. A juvenile (Hoita) bag with 0.8 mm lining is attached under the trawl in front of the cod-end in order to collect juvenile shrimp < 10 mm in the catch.

Trawl geometry and behaviour of the trawl were monitored using *Scanmar* trawl sensors. The Norwegian vessels used standard *Steinshamn* W9 bottom V trawl doors with an area of 6.7 m^2 and a weight of 2 250 kg. "Strapping" – a rope 150-180 m in front of the doors locks the distance the trawl doors to approximately 50 m – is used. The towing time is 15 min. GPS positions were used to calculate towed distance. A speed sensor (symmetry) was used on all bottom hauls, giving information about the direction and amount of currents entering the trawl and making it possible to tow at the right speed and geometry in proportion to underwater crosscurrents by adjusting wires or warps to compensate a skewed trawl. Other trawl settings are described in detail in a separate manual for rigging of trawl and trawl equipment (Engås, 1995).

Sampling routines
For each haul on board Norwegian vessels, samples of 250-300 adult shrimp specimens are taken from the main bag, sorted by sexual characteristics, and measured by calliper to the nearest mm below (carapace length, cpl, as defined in Allen (1959); McCrary (1971)). A sample of up to 100 juvenile individuals is taken from the Hoita bag and measured the same way as the adults. Shrimp sampling on board Russian vessels is done in a similar manner.

Russian and Norwegian scientists use different database systems (BioFox and Sea2Data, respectively) to register biological data from marine animal surveys. At the end of the survey the Russian ecosystem data are converted and included in the Norwegian database system; however, it has to date not been possible to convert the Russian shrimp length data, so that normally only total weight per haul is given. The length- and sex frequency distribution in the samples was weighted by total catch and stratum area to obtain estimates of the overall distribution.

Area stratification
Data from the sampling were stratified by depth and area as in Fig. 3. Five main areas are identified which each are further sub-divided into 6 depth strata (0-600 m). The depth strata boundaries follow depth contours obtained from the GEBCO world bathymetry database (http://www.gebco.net). The individual strata were constructed using ArcGIS software; then each stratum's area was calculated in km^2 using an equal area projection (Europe Albers Conic) (Table 1, Fig. 4).

Swept area analysis
The catch in each tow divided by the swept area represents a sample of shrimp density in a stratum. From these samples the mean and standard error of the density in each stratum was calculated and multiplied by the area of the stratum to give an estimate of stratum biomass and abundance. Standard error was calculated as $B * 0.985$ Cochran (1977) for strata with only one tow. The means and their standard errors for the strata were summed to give the overall values for the survey area. The calculations were done using the SAS statistical software (Anon., 1988).

Results

Biomass
The biomass indices of survey 1 and 2 have fluctuated without trend over their respective time periods covered (Fig. 5). The most recent survey series (survey 3) has increased substantially since a low in 2016 to reach its highest value in 2019. In general, the entire survey area of the Ecosystem survey (survey 3) is covered in all years, however, due to heavy ice conditions in 2014 the northern part of the area (stratum 3, see SCR Doc. 17/68) was not covered. For the 2004-2013 survey period this area accounts for on average 13% of the biomass (range: 8-27%). The 2014 biomass for stratum 3 was estimated by calculating the average ratio of biomass density in stratum 3 to biomass density in the remaining survey area for the 2009-

2013 period and applying this average to the density of the 2014 surveyed area. Estimates of variance for stratum 3 was taken as the variance of the 2009-2013 estimates for stratum 3. A similar method incorporating 2015 to 2017 data was used to compensate for missing coverage due to vessel malfunction of stratum 5 and stratum 4 in 2018 and 2019 respectively (Fig. 10).

Demography
Overall size distributions (Fig. 11) indicate a relatively large amount of smaller shrimp in 2004 which likely based the increase in stock biomass until 2006 (Fig. 4). The recruitment index – estimated abundance of shrimp at 13-16mm CL supposed to enter the fishery in the following one-two years decreased since 2004 (Fig. 12). Nevertheless, total biomass increased in 2009 and 2010 questioning the predictive capability of the recruitment index. The demographic information was not updated since 2009 (additional recruitment information for this period is available from the Russian survey analyses)

Distribution
The spatial distribution of shrimp biomass has changed (Fig. 6,7,10). Since 2004 the areas of high shrimp density are gradually found further east in the Barents Sea (Fig. 10). A noticeable shift is seen from 2007-09 when the percentage of biomass in stratum 2 declines while that of area 4 increases (Fig 7 upper). At the same time no significant changes in depth distribution were seen (Fig 7 lower). The average densities have increased times four in stratum 4 between 2007 and 2010 while those of stratum 2 have declined substantially (Fig 9 upper). In 2017-19 shrimp is again available in commercial attractive densities over larger areas of the Barents Sea, however, the highest concentrations are still found on the more easterly fishing grounds.

Temperature
In the ecosystem survey, shrimps were only caught in areas where bottom temperatures were above 0°C. Highest shrimp densities were observed between zero and 4°C, while the limit of their upper temperature preference appears to lie at about 6-8°C. The warming of the western Barents Sea coincides with the shift in shrimp distribution eastwards (SCR Doc 18/66), thus temperature is probably a factor in explaining the observed change in spatial distribution.

Table 3. Estimated biomass, abundance and mean weight of the total and fishable (>16 mm cpl) stock and of recruits (13-16 mm cpl). Demografic data since 2009 not analysed.

	Biomass (ktons)				Abundance (#10^9)			Mean weight (g)		
Year	Total	Fishable	Recruites	CV (%)	Total	Fishable	Recruites	Total	Fishable	Recruites
2004	365	261	97	9	98	47	44	3.73	5.54	2.21
2005	527	446	78	22	121	85	33	4.35	5.26	2.38
2006	605	517	85	8	135	97	35	4.48	5.34	2.45
2007	474	426	46	7	90	71	17	5.27	6.02	2.67
2008	354	317	34	9	69	52	14	5.14	6.05	2.46
2009	424	343	-	10	-	-	-	-	-	-
2010	597	482	-	9	-	-	-	-	-	-
2011	547	442	-	9	-	-	-	-	-	-
2012	602	487	-	8	-	-	-	-	-	-
2013	512	413	-	7	-	-	-	-	-	-
2014	380	307	-	7						
2015	401	324	-	7						
2016	318	257	-	9						
2017	529	428	-	8						
2018	619	501	-	10						
2019	782	632	-	15						

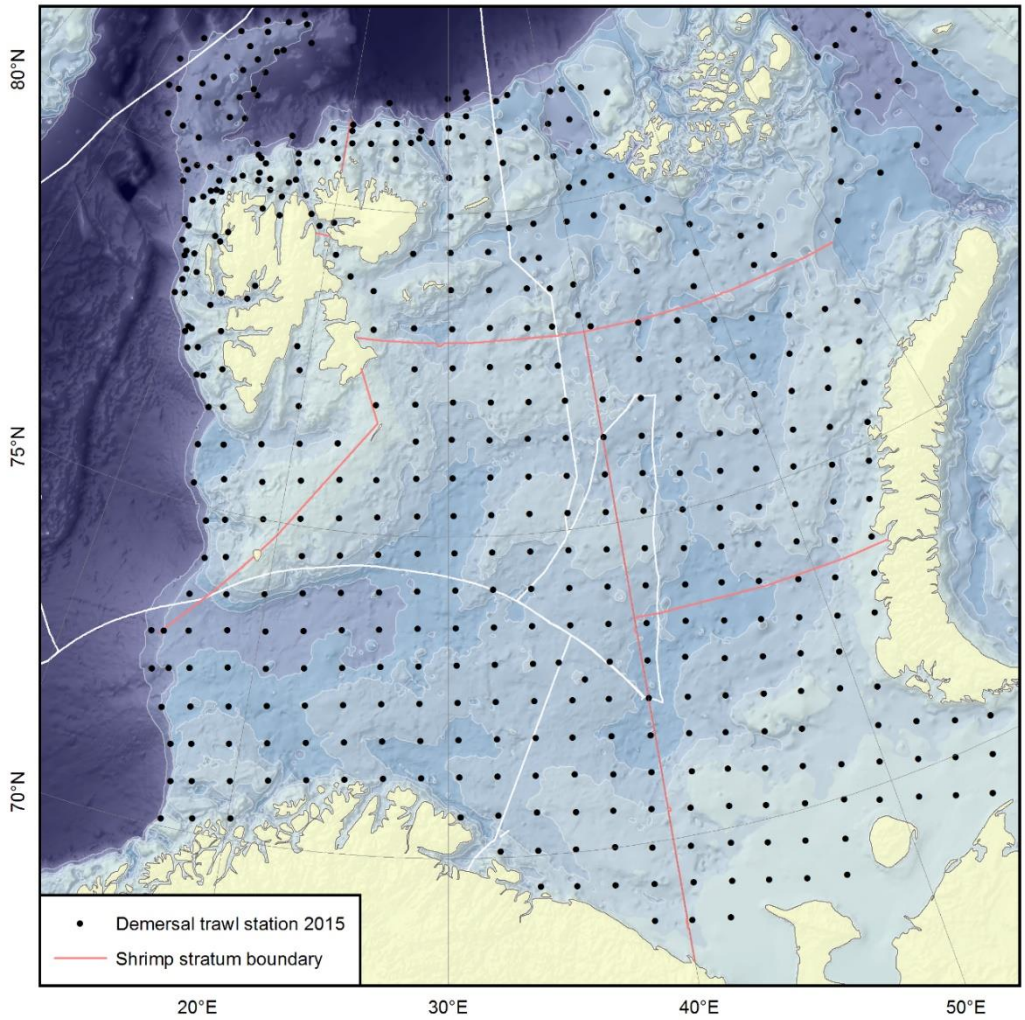

Figure 1. Sampling locations of the 2016 Norwegian-Russian ecosystem survey in the Barents Sea.

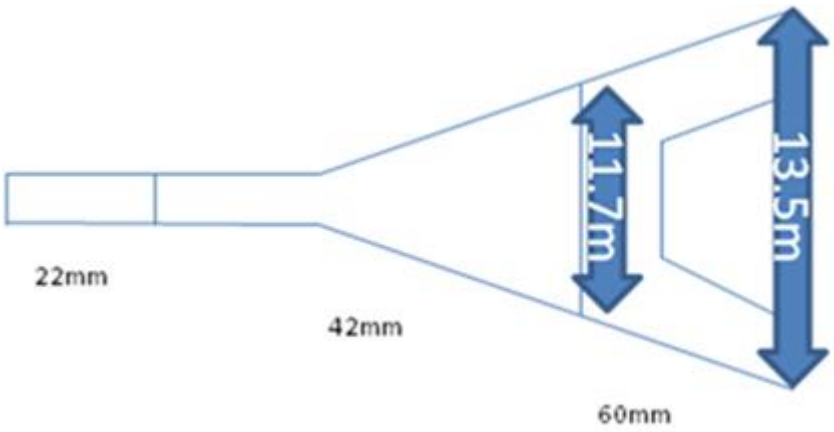

Figure 2. Schematic drawing of a Campelen 1800 survey bottom trawl with 22 mm mesh size in the cod-end, 42 mm in the mid-section, and 60 mm in the trawl opening. The width of the trawl opening (11.7 m) and wing spread (13.5 m) is also indicated.

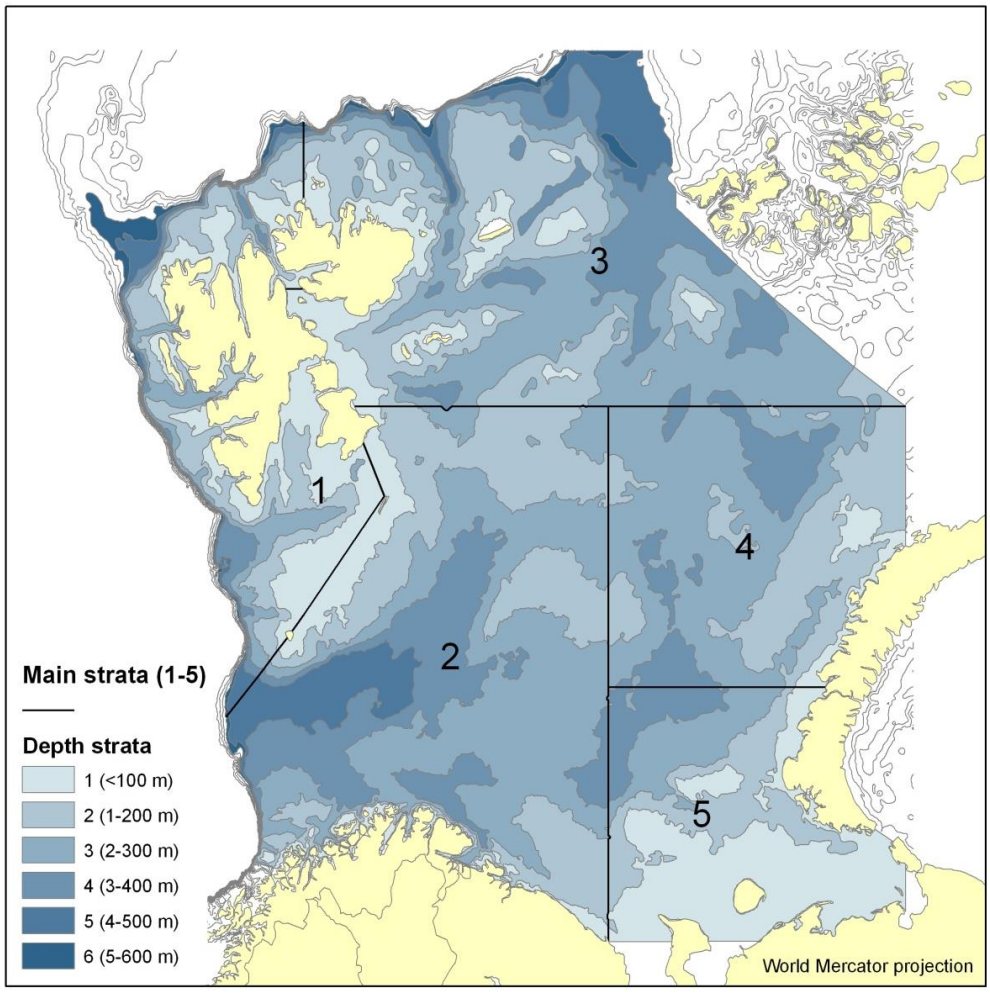

Figure 3. The survey stratification scheme. Each stratum is given a code for [main area]+[depth stratum within]; e.g. [1.3] indicates main stratum = 1 and depth stratum = 3, i.e. covering depths from 201 to 300 m (see also Table 1).

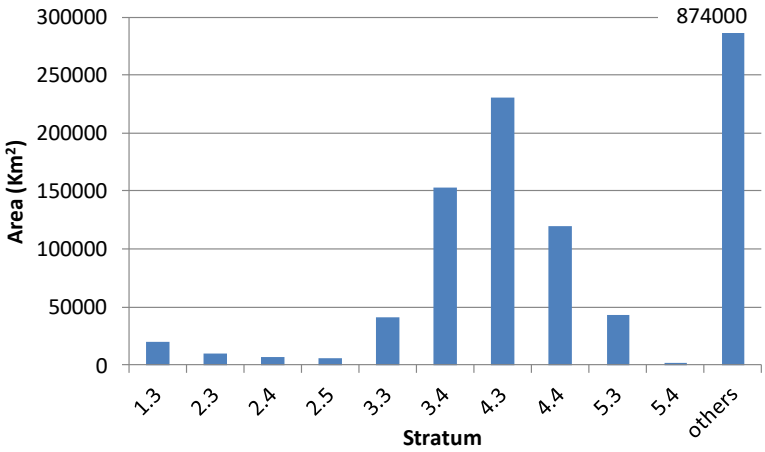

Figure 4. Areas of the 10 most important strata (code: see Table 1 and Fig. 3 for definition).

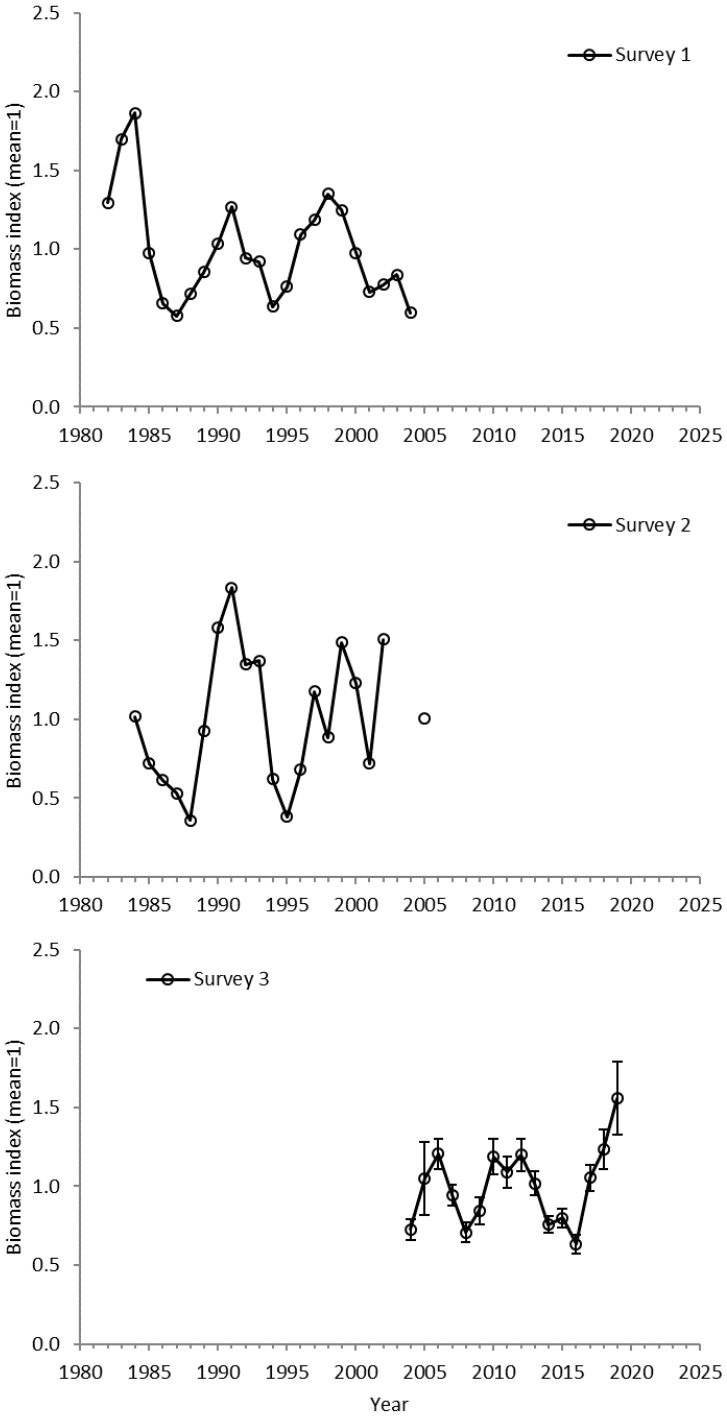

Figure 5. Indices of annual mean biomass from survey 1: The Norwegian shrimp survey 1982-2004; survey 2: The Russian shrimp survey 1984-2002 and 2005; and survey 3: The joint Norwegian-Russian ecosystem survey since 2004.

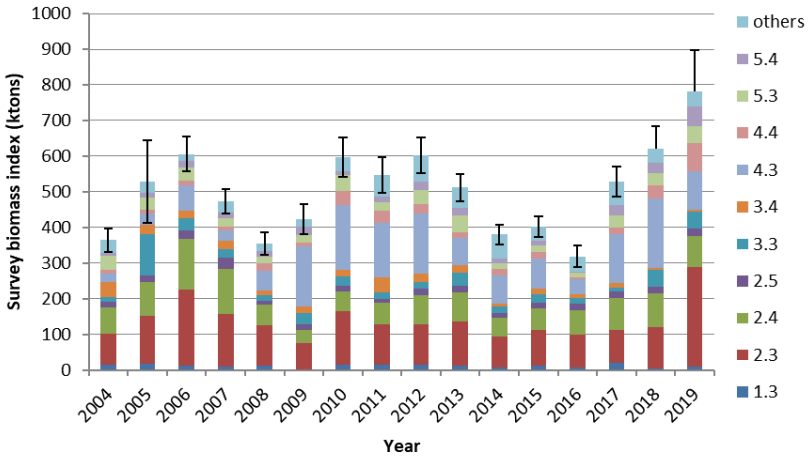

Figure 6. Estimated mean index of biomass by year and sub-strata (code: see Table 1 and Fig. 3 for definition). Error bars indicate +/- one Standard Error of the overall estimate.

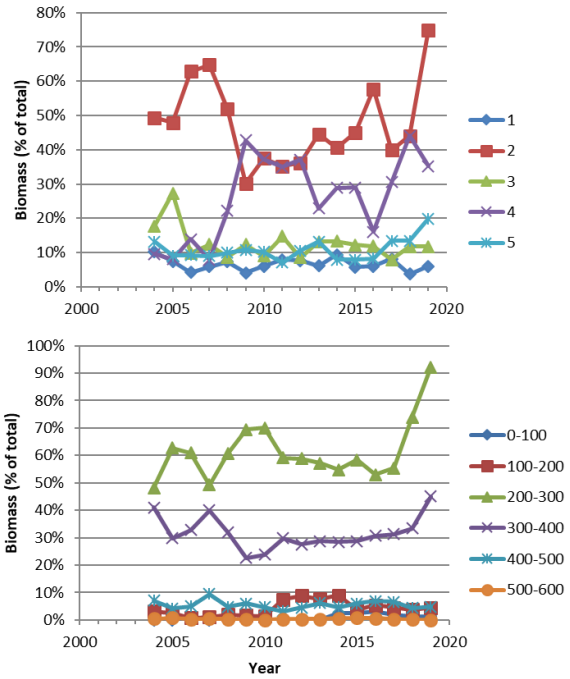

Figure 7. Percentage of total biomass. *Upper*: by main strata (see fig 3). *Bottom*: by depth strata.

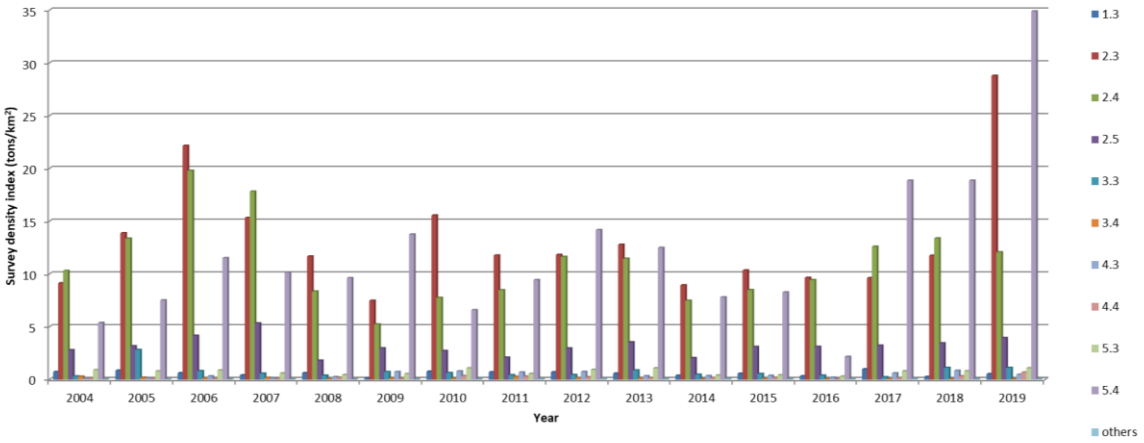

Figure 8. Estimated mean biomass density by year and strata (code: see Table 1 and Fig. 3 for definition)

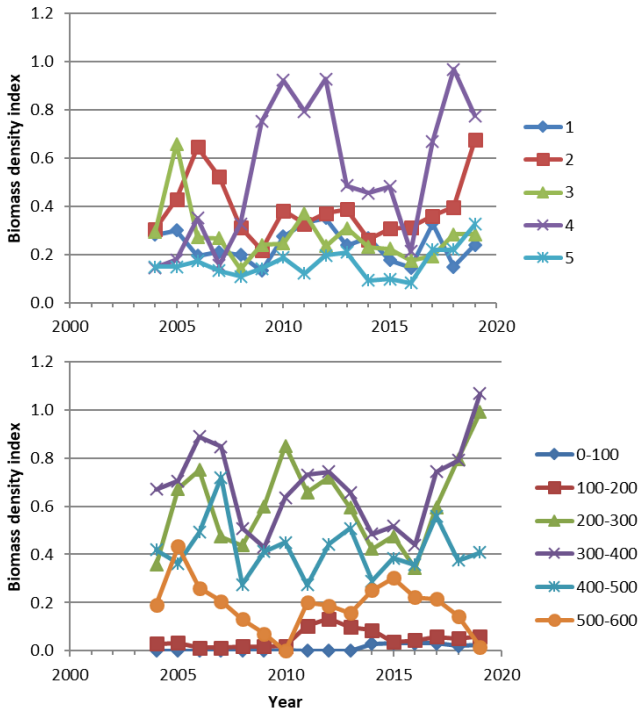

Figure 9. Estimated mean biomass density index. *Upper*: by main strata (see fig 3). *Bottom*: by depth strata.

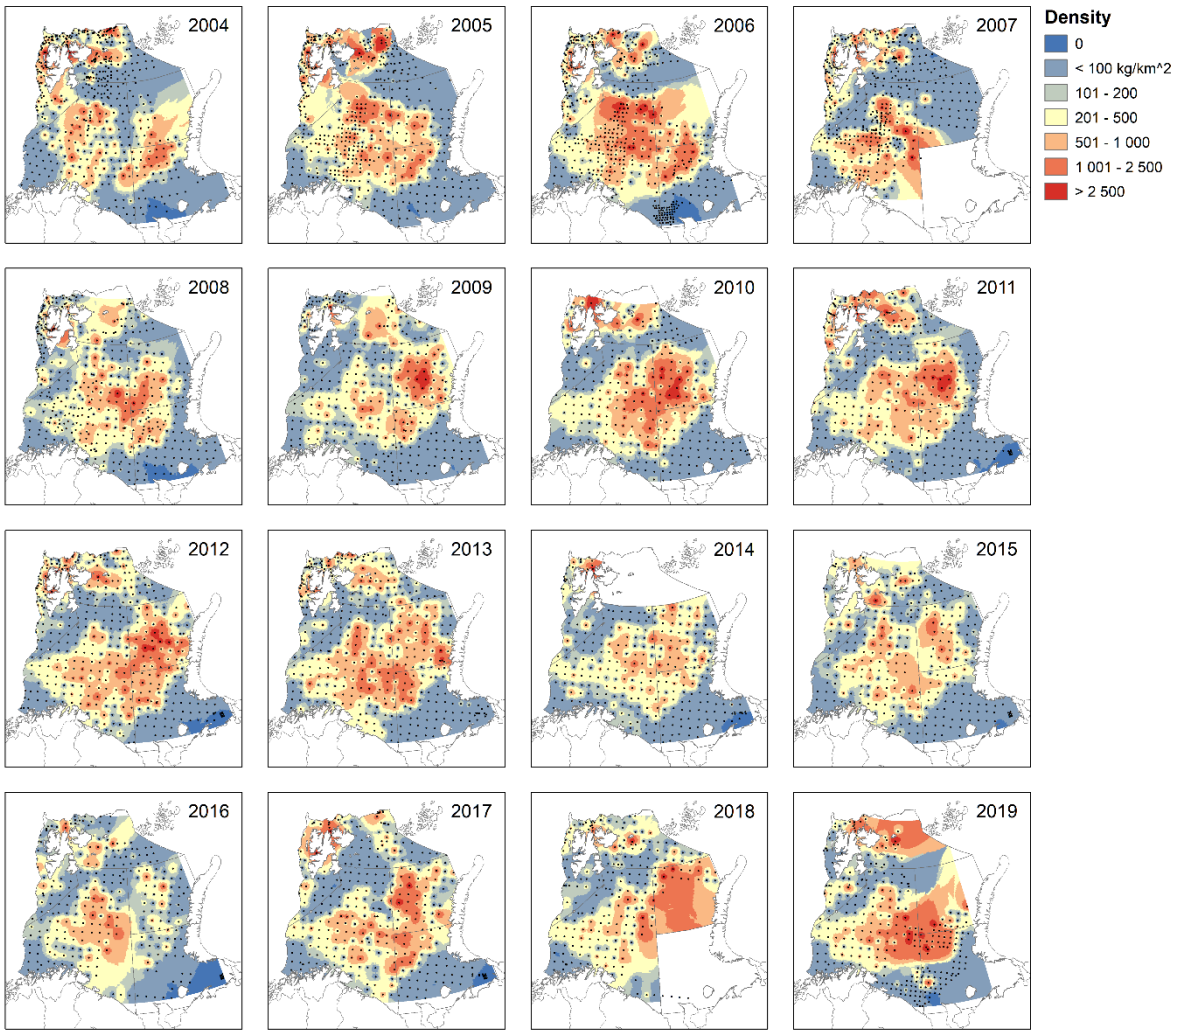

Figure 10. Shrimp density by year from *inverse distance weighted* interpolation (e.g. Fisher *et al.*, 1987) between trawl stations (black dots) (Europe Albers Equal Area Conic projection). (no data for stratum 3 in 2014 due to ice conditions; no data for stratum 5 in 2018 and 4 in 2019 due to vessel malfunction).

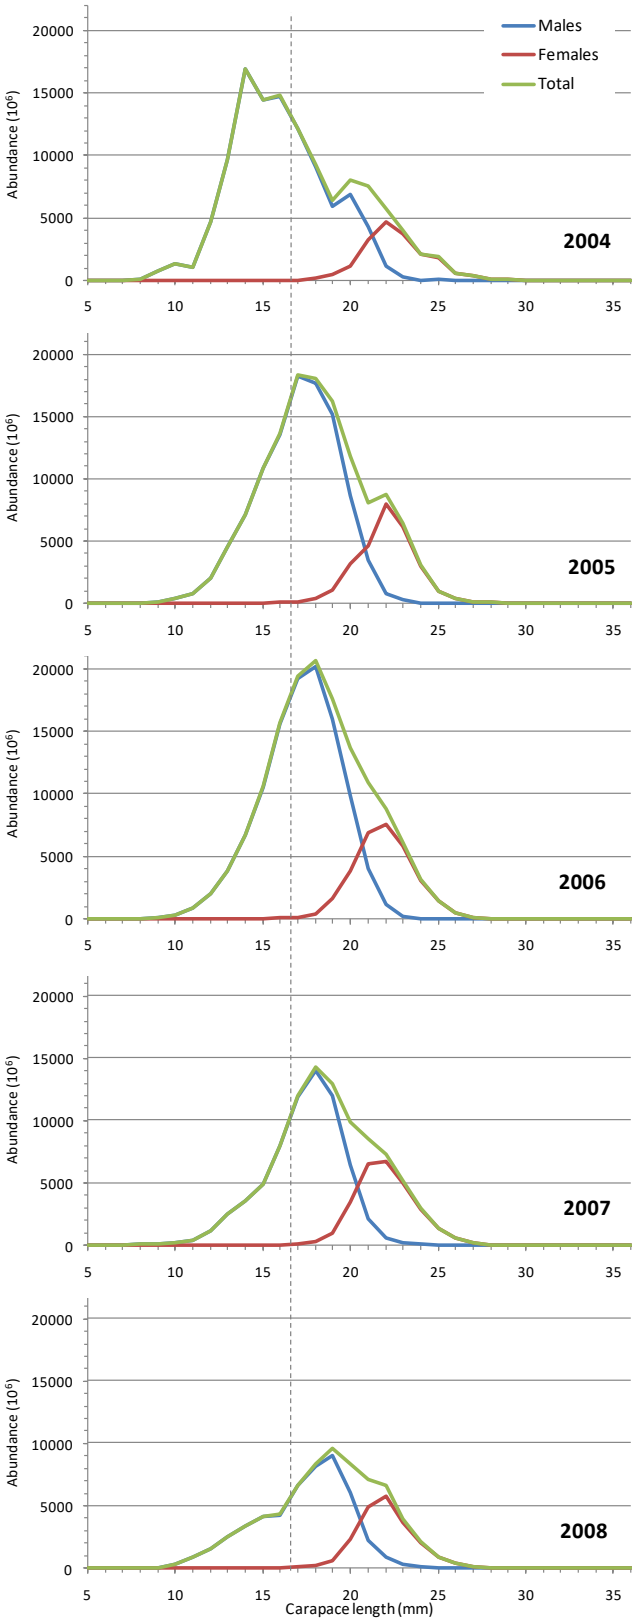

Figure 11. Shrimp in the Barents Sea: overall size distribution of males, females and total 2004-2008. (No analyses since 2009)

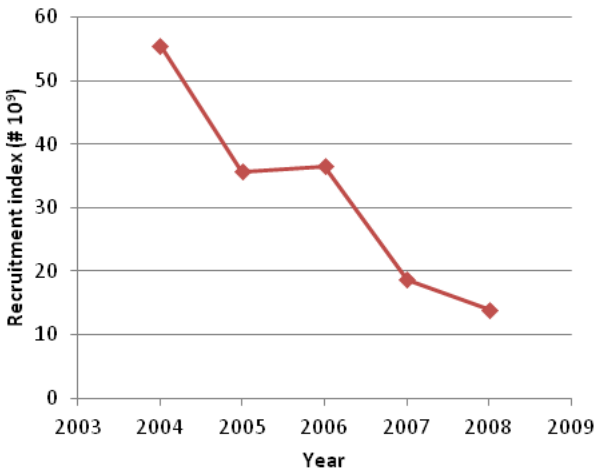

Figure 12. Index of recruitment: estimated mean abundance of shrimp at size 13-16 mm cpl 2004-2008. (No analyses since 2009).

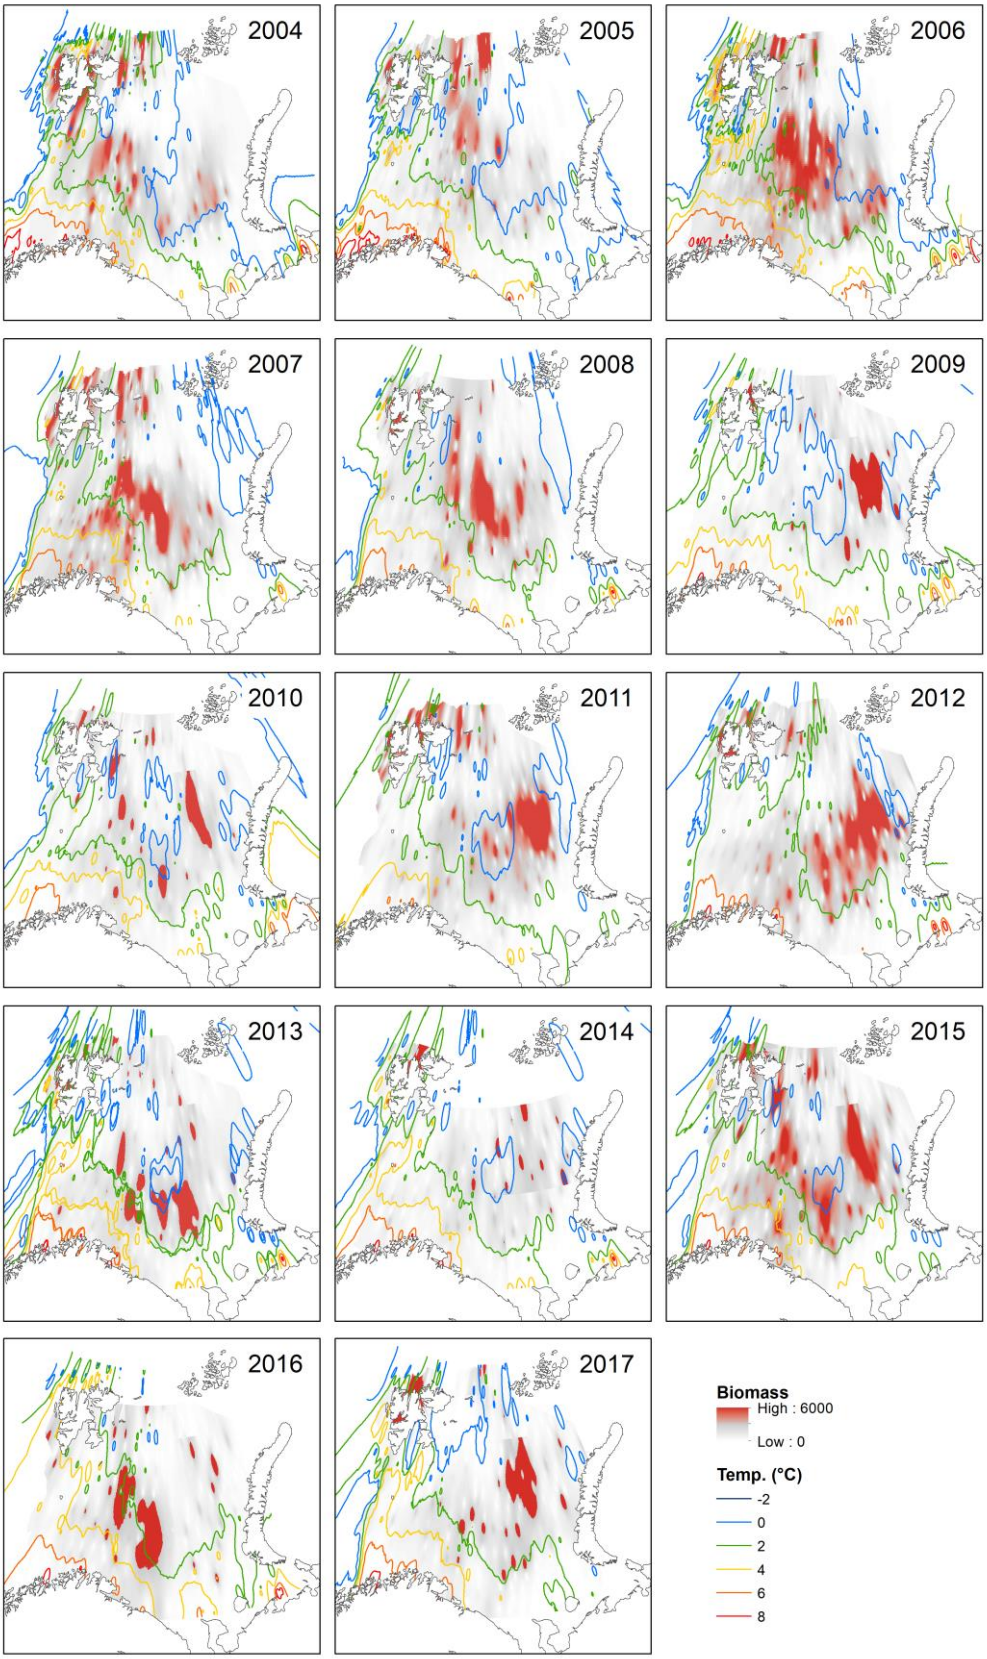

Figure 13. Bottom temperature contour overlaid shrimp density distributions (see Fig. 7) from ecosystem surveys since 2004 (temperature data available for 2018 and 2019).
