Hydrographic conditions off West Greenland in 2019

Boris Cisewski, Thünen Institute of Sea Fisheries, Germany

Abstract

An overview of the atmospheric and hydrographic conditions off West Greenland in autumn 2019 is presented. In winter 2018/2019, the NAO index was positive (2.09) for the sixth consecutive winter. The annual mean air temperature at Nuuk Weather Station in West Greenland was 0.4°C in 2019, which was 1.8°C above the long-term mean (1981-2010). The core properties of the water masses of the West Greenland Current (WGC) are monitored at two standard NAFO/ICES sections across the western shelf and continental slope of Greenland near Cape Desolation and Fyllas Bank. However, the Fyllas Bank Section had to be abandoned due to severe weather conditions in autumn 2019. The properties of the Irminger Sea Water (ISW) are monitored in the 75-200 m layer at Cape Desolation Station 3 (CD3). In 2019, the water temperature and the salinity in the 75-200 m layer at CD3 was 5.98°C and 34.92, which was 0.26°C above and 0.01 below the long-term mean, respectively. The properties of the North Atlantic Deep Water (NADW) in the Deep Boundary Current west of Greenland are monitored at 2000 m depth at Cape Desolation Station 3. In 2019, the temperature and salinity of the NADW were 3.11°C and 34.92 and were 0.22°C and 0.01 above the long-term mean, respectively.

Introduction

The water mass circulation off Greenland comprises three main currents: Irminger Current (IC), West Greenland Current (WGC) and East Greenland Current (EGC). The EGC transports ice and cold low-salinity Surface Polar Water (SPW) to the south along the eastern coast of Greenland. On the inner shelf the East Greenland Coastal Current (EGCC), predominantly a bifurcated branch of the EGC, transports cold fresh Polar Water southward near the shelf break (Sutherland and Pickart, 2008). The IC is the northward flowing component of the North Atlantic subpolar gyre. It transports relatively warm water that mixes with colder water transported by the EGC from the Arctic Ocean. South of the Denmark Strait (DS) the current bifurcates. While a smaller branch continues northward through the DS to form the Icelandic Irminger Current, the bulk of the current recirculates to the south and transports salty and warm ISW southward along the eastern continental slope of Greenland. After EGC and IC converge, they turn around the southern tip of Greenland, form the WGC and propagate northward along the western coast of Greenland. During this propagation considerable mixing between two water masses takes place and the ISW gradually deepens (Clarke and Gascard, 1983; Myers et al., 2009). The WGC carries the water northward and consists of two components: a cold and fresh inshore component, which is a mixture of the SPW and melt water, and a saltier and warmer ISW offshore component. The WGC transports water into the Labrador Sea, and hence is important for Labrador Sea Water formation, which is an essential element of the Atlantic Meridional Overturning Circulation. The dynamics of the current is monitored yearly in autumn at two standard ICES/NAFO oceanographic sections across the slope off West Greenland (Figures 1, 2).
Materials and Methods

The German groundfish survey off Greenland has been conducted since 1981, aiming at monitoring groundfish stocks, cod and redfish in particular. The monitoring is carried out by the Thünen-Institute of Sea Fisheries (TI-SF) and reveals significant interannual and long-term variability of both components of the WGC. Hydrographic profiles were collected with a Sea-Bird 911plus CTD attached to a 12-bottle water sampler. The hydrographic database consisted of 43 hydrographic stations sampled between September 30 and November 11, 2019, from R/V Walther Herwig III. Study area and station locations are shown in Figure 2. For in-situ calibration, salinity samples were analyzed with an OPTIMARE Precision Salinometer (OPS) immediately after the cruise. The sea level pressure (SLP) and its anomalies during the winter months (December through March) were taken from NCEP/NCAR reanalysis data available from the NOAA-CIRES Climate Diagnostics Centre (http://www.cdc.noaa.gov/). To describe the pattern of SLP over the North Atlantic, Hurrell’s winter (December through March) station based index of the North-Atlantic Oscillation was used (Hurrell, 1995). This index based on the difference of normalized sea level pressure (SLP) between Lisbon, Portugal and Reykjavík, Iceland since 1864 and is available at https://climatedataguide.ucar.edu/climate-data/hurrell-north-atlantic-oscillation-nao-index-station-based.

Air temperature at Nuuk station (Table 1) on the western coast of Greenland was used to characterize the atmospheric conditions in 2019. Annual and monthly mean values were obtained from the Danish Meteorological Institute (Cappelen, 2020). The climatological mean of this time series were referenced to 1981-2010. Information about sea surface temperature anomalies was provided by NOAA/ESRL Physical Science Division, Boulder, Colorado, based on objective interpolation product (NOAA OI SST, Reynolds et al., 2002).

Results and Discussion

Atmospheric conditions in 2019

The variability of the atmospheric conditions over Greenland and the Labrador Sea is driven by the large scale atmospheric circulation over the North Atlantic, which is normally described in terms of the North Atlantic Oscillation (NAO). During a positive NAO strong northwest winds bring cold air from the North American continent and cause negative anomalies of the air temperatures over Greenland, Labrador Sea and Baffin Bay (Hurrell and Deser, 2010). During a negative NAO, the westerlies slacken and the weather is normally milder over the whole region. In winter 2018/2019, the NAO index was positive (2.09) for the sixth consecutive winter (Figure 3). Figure 4a shows the winter sea level pressure (SLP) averaged over 30 years (1981-2010), mainly dominated by the Iceland Low and the Azores High. Both the Icelandic Low and the Azores High were strengthening, resulting in a greater than normal increase in pressure difference over the North Atlantic sector during the winter of 2018/2019 (Figure 4b). The resulting negative anomalies in the north and the positive in the south reveal characteristics typical of a positive NAO (Figure 4c). Air temperature at Nuuk was used to characterize the atmospheric conditions in 2019. Annual and monthly mean values were obtained from the Danish Meteorological Institute (Cappelen, 2020). In 2019, the monthly mean air temperatures were higher than the long-term mean except for December (Figure 5). The annual mean temperature at Nuuk was -0.4°C in 2019, which was 1.8°C above the long-term mean (1981-2010) (Figure 6).

Hydrographic Conditions in 2019

The annual sea surface temperature (NOAA OI SST) anomalies for 2019 indicate positive anomalies in the Northwestern Atlantic with highest values occurring in the central Labrador Sea (Figure 7). The core properties of the water masses of the WGC are monitored at two standard NAFO/ICES sections across the western shelf and continental slope of Greenland near Cape Desolation and Fyllas Bank. However, the Fyllas Bank section has to be abandoned due to severe weather conditions. The Cape Desolation section is located 300 km northwest from the southern tip of Greenland. At this section a strong surface front separates SPW on the shelf from ISW offshore (Figure 8). In autumn, the temperature of the upper layer is well above zero (Tmin = 3.81°C) (Figure 8a). A salinity of less than 33.0 was observed at station 248 (Figure 8b). The most offshore station of the section done in 2019 (Station 251) corresponds to the standard Cape Desolation Station 3 (CD3), which has been reported in ICES Working Group on Oceanic Hydrography (WGOH) since 2001. In
2019, the water temperature of the upper 700 meters was higher than its long-term mean, whereas the salinity reveals positive anomalies in the uppermost 100 m and slightly negative anomalies between 100 and 700 m water depth (Figures 9a, b). In 2019, the water temperature and the salinity in the 75-200 m layer at CD3 was 5.98°C (Figure 10a) and 34.92 (Figure 10b), which was 0.26°C above and 0.01 below the long-term mean. The properties of the NADW in the deep boundary current west of Greenland are monitored at 2000 m depth at CD3. The temperature and salinity of the NADW underwent strong interannual variability during the 1980s (figure 11). Since the beginning of the 1990s, both characteristics were decreasing and reached their minimum values in 1998 and 1997, respectively. After that, the temperature of the NADW revealed a positive trend until 2019, whereas the salinity rather stagnated between 2007 and 2019. In 2019, the temperature and salinity of the NADW were 3.11°C and 34.92 and were 0.22°C and 0.01 above the long-term mean, respectively.
