

SCIENTIFIC COUNCIL MEETING – JUNE 2020

**Assessment of Thorny Skate (*Amblyraja radiata* Donovan, 1808)
in NAFO Divisions 3LNO and Subdivision 3Ps**

by

Abstract

Available information on the fishery, management, biology, and assessment of Thorny Skate in NAFO Divisions 3LNO and Subdivision 3Ps was reviewed to determine the status of this stock. Based on the continuous distribution of this species, and lack of physical barriers between Divs. 3LNO and Subdiv. 3Ps, Thorny Skate in Divs. 3LNOPs is considered to constitute a single stock. In 2012-2018, an average of 3 805 tons of Thorny Skate from Divs. 3LNO was commercially landed. STACFIS-agreed total landings from Divs. 3LNO were 3 697 t in 2019. Reported landings in Subdiv. 3Ps averaged 460 t in 2012-2018, and totaled 889 t in 2019. An Index of Fishing Mortality for Divs. 3LNO increased from the late 1980s to a peak of 32% in 1997, then decreased and stabilized at approximately 17% during 1998-2004. In 2005-2011, this Index averaged 6%, and remained around 4% since 2012. The Fishing Mortality Index in Subdiv. 3Ps was $\leq 2\%$ since 2010. After a drastic decline over 1985-1995, Canadian spring research surveys indicated that biomass and abundance of Thorny Skate in Divs. 3LNO were relatively stable at low levels. Thorny Skate distribution in Divs. 3LNOPs over 2010-2019 continued to be concentrated on the southwestern Grand Banks, in Subdiv. 3Ps, and northward along the edge of the Bank.

Introduction

Thorny Skates (*Amblyraja radiata* Donovan, 1808) are widely distributed in temperate and Arctic waters of the North Atlantic. In the western Atlantic, Thorny Skate are distributed from Greenland to South Carolina, with the centre of distribution on the Grand Banks (Fig. 1) in NAFO Divisions 3LNO. Commercial catches of skates consist mainly of Thorny Skate, with about 95% in Canadian skate catches (Kulka and Miri 2007); which is similar to the 97-99% of Thorny Skates observed in the Canadian spring survey (see **Survey Catch Composition – Other Skates** below). In the EU-Spain research survey over 2014-2016 in Divs. 3NO, Thorny Skate comprised approximately 90% of the skate taken in the survey (González-Costas *et al.* 2020). Thus, the skate fishery on the Grand Banks can be considered a directed fishery for Thorny Skate.

Fishery and Management

TAC Regulation

Thorny Skate came under quota regulation in 1995, after a directed skate fishery was established in 1994 by Canada in its Exclusive Economic Zone (EEZ). A Total Allowable Catch (TAC) of 5 000 tons for Divisions 3LNO and 1 000 t for Subdivision 3Ps were adopted by Canada in 1995. In 1996, the TAC was raised to 6 000 t for Divs. 3LNO and 2 000 t for Subdiv. 3Ps. In 1997, the TAC was reduced to 1 950 t for Divs. 3LNO, and 1 050 t for Subdiv. 3Ps.

Outside Canada's EEZ, catch was unregulated until September 2004, when the Northwest Atlantic Fisheries Organization (NAFO) Fisheries Commission set a TAC of 13 500 t for 2005-2009 in the NAFO Regulatory Area (NRA) of Divs. 3LNO (Fig. 2). This TAC was lowered to 12 000 t for 2010-2011, and to 8 500 t for 2012. The TAC was further reduced to 7 000 t for 2013-2020. The TAC for Subdiv. 3Ps has been maintained at 1 050 t.

Landings Trends

On the Grand Banks, Kulka and Mowbray (1998) reported that significant bycatch of skates have been taken since commencement of offshore fishing in the late 1940s, initially by non-Canadian fleets and later by Canadian vessels. Prior to the mid-1980s, non-Canadian fleets comprised the largest component of offshore fisheries on the Grand Banks, and took several thousand tons of skate as bycatch each year. The bycatch derived primarily from the Greenland Halibut fishery and from the Canadian mixed fishery for Thorny Skate, White Hake (*Urophycis tenuis*), and Monkfish (*Lophius americanus*). Kulka and Mowbray (1998) estimated that approximately 5 000 t, on average, were discarded annually by Canadian fleets during the 1980s and early 1990s, although only a few hundred tons were recorded in Canada's annual landings statistics during that period.

Catches for Divs. 3LNO (Table 1; Fig. 2) increased in the mid-to-late 1980s with the commencement of a directed fishery for Thorny Skate. In 1985, Spain began targeting skate in a non-regulated fishery in the NRA (Junquera and Paz 1998; del Río and Junquera 2001). During 1985-1991, landings averaged 17 058 t and peaked at approximately 28 400 t in 1991 (STATLANT-21A). This fishery was mainly prosecuted by Spain, Portugal, USSR, and the Republic of Korea. Non-Canadian landings declined significantly to 5 059 t in 1992 (Table 1). In 2000, Russia joined the directed fishery for Thorny Skate. Due to a new Canadian-directed fishery that began in 1994, Canadian landings increased during 1994-1999, to an average of 1 590 t (Simpson and Miri 2012). Since 2000, total reported landings of skate by all countries in Divs. 3LNO declined (Fig. 2). In 2012-2018, an average of 3 831 t of Thorny Skate was landed from Divs. 3LNO. STACFIS-agreed landings from Divs. 3LNO in 2019 totaled 3 697 t.

In Subdiv. 3Ps, STATLANT-21A data indicated that Canadian fleets reported the majority of Thorny Skate landings, while St. Pierre and Miquelon (EU-France) annually reported smaller amounts of landings (Table 2; Fig. 2). Prior to 1994, Canadian landings of Thorny Skate in Subdiv. 3Ps rarely exceeded a few hundred tons. Total reported landings in Subdiv. 3Ps averaged 1 328 t from 1994-2008, 500 t from 2009-2011, and 460 t over 2012-2018. In Subdiv. 3Ps, reported Canadian landings totaled 889 t in 2019.

Commercial Size

Sampling of Canadian commercial catches by Canadian At-Sea Fisheries Observers indicated that Thorny Skates trawled in the Div. 3L redbfish (*Sebastes* sp.) fishery varied between 27-93 cm in 2016-2019, including modes of 35-40, 56, 62-66, and 72-82 cm (Fig. 3a; see Simpson and Miri 2012 for previous years). Skates caught by Canadian trawlers in the Divs. 3NO Yellowtail Flounder (*Limanda ferruginea*) fishery in 2016-2019 were 24-101 cm, with no dominant size classes observed. In 2017, Thorny Skates trawled in the Div. 3O Witch Flounder (*Glyptocephalus cynoglossus*) fishery ranged between 42-100 cm, with a mode of 80 cm. Skates trawled in the

Divs. 2J3KL Greenland Halibut (*Reinhardtius hippoglossoides*) fishery in 2018 varied between 31-88 cm in length, with modes of 48, 53, and 63 cm.

From skate-directed trawl fisheries (280 mm mesh) in the NRA of Divs. 3LNO over 2013-2019, EU-Spain reported a range of 15-100 cm TL skates (no distinct modes), with a small number of young-of-the-year (≤ 21 cm) caught in 2013-2014 and 2017-2018 (Fig. 3b; see Simpson and Miri 2012 for previous years). In 2013, EU-Portugal caught 26-85 cm TL skates (mode of 49-50 cm) in Div. 3N (280 mm mesh).

In other directed trawl fisheries (130-135 mm mesh) of Divs. 3LNO (NRA) in 2013-2019, EU-Portugal reported skate bycatch ranging from 25-88 cm TL, including modes of 46-49, 60-64, and 72-76 cm (Fig. 3c; see Simpson and Miri 2012 for previous years). EU-Portugal did not sample Divs. 3LNO skate bycatch in 2014-2016 and 2018, while EU-Spain have not done so since 2009). Russia sampled Thorny Skates during the Div. 3LN Greenland Halibut fishery in 2012, ranging from 24-78 cm TL (Fig. 3c; see Simpson and Miri 2012 for previous years). In the Divs. 3LO redfish fishery over 2013-2016, Russia reported skate bycatch of 35-89 cm. Russia sampled only 5 and 14 specimens in 2017 and 2018 (respectively). In 2019, Russia sampled 494 skates as bycatch in Divs. 3LNO ranging from 31-95 cm TL, with mean lengths of 56, 64, and 71 cm (respectively per Division).

Research Survey Data

Canadian Spring Surveys

Stratified-random surveys have been conducted by Canadian research vessels in the spring (April-June) of each year from 1971 to 2019. A summary of the stratified-random survey design adopted by the DFO-NL Region can be found in Doubleday (1981). While survey design has remained constant, additional strata have been included, and some of the original strata have been modified (Bishop 1994). A significant change in the surveys was the addition of shallower and deeper strata after 1993. Additional causes of variation in spring survey coverage are discussed in detail most recently by Rideout (2020), and Rideout and Ings (2020). The spring survey can be split into three time series, based on the trawl used in each period: 1971-1982 (Yankee 41.5), 1983-1995 (Engel 145), and 1996-2019 (Campelen 1800; McCallum and Walsh 1996). Conversion factors exist for the Engel to Campelen gear change (Simpson and Kulka 2005), but not for the Yankee to Engel gear change. In 2006, most of Subdiv. 3Ps was not surveyed, and only shallow strata in Divs. 3NO were surveyed, due to Canadian research vessels' mechanical difficulties. Therefore, survey estimates for that year are not comparable to others in the Campelen time series. In 2015 and 2017, Div. 3L was not completely surveyed, thus impacting biomass and abundance estimates of Thorny Skate.

Historical abundance and biomass indices from Canadian spring surveys in Divs. 3LNOPs are provided in Table 3(a,b) and Figures 4a and 5. Since the mid-1990s, spring biomass indices for Thorny Skate in Divs. 3LNOPs were generally increasing, following a declining trend over 1985-1995. In 2018, biomass estimates for Thorny Skate in Div. 3L, 3N, and 3O were 16 983 t, 40 868t, and 76 215 t (respectively). The biomass index in Div. 3N had increased since 2015 but declined in 2019 to 19 019 t. The biomass index in 2019 was 72 605 t in Div. 3O, slightly above the 2013-2017 average of 69 354 t. However, the 2019 biomass estimate of 11 860 t in Div. 3L was well below the 2018 value and the 2013-2017 average of 34 743 t. In Subdiv. 3Ps, the biomass index was 48 339 t and 37 211 t in 2018 and 2019 respectively. In 2019 the index declined and was below the 2014-2018 average of 39 903 t.

Canadian Fall Surveys

Annual stratified-random fall surveys have been conducted by Canada in Div. 3L from 1981 to 2019. In 1990-2019, fall surveys also extended onto the southern Grand Banks in Divs. 3NO. Canadian surveys were originally conducted with an Engel 145 trawl, then a Campelen 1800 trawl in 1995-2019. Although fall surveys sample deeper maximum depths (~1 450 m) than those in spring (~730 m), they do not cover the entire stock area, and thus are not considered spatially complete. For this reason, Canadian spring surveys are used as the primary source of biomass and abundance estimates for Thorny Skate. However, fall indices are still considered

in assessments of this stock, because this survey is conducted when a greater proportion of Thorny Skate is available to survey trawls. During fall, Thorny Skates are concentrated on the shelf; in spring, part of this population has moved to the shelf edge, and a proportion apparently moves outside of the survey area (Kulka *et al.* 2004). When using spring estimates of biomass and abundance to examine trends in this stock, it is assumed that the proportion of skate that moves outside of the surveyed area remains consistent between years. Additional causes of variation in fall survey coverage are discussed in detail most recently by Rideout (2020), and Rideout and Ings (2020).

Historical abundance and biomass indices from Canadian fall surveys in Divs. 3LNO are provided in Table 4(a,b) and Figure 4b. Fall abundance indices of Thorny Skate remained stable at very low levels since 1995. Divs. 3NO were not surveyed in fall 2014, as well as deep-water strata (>732 m) of Div. 3L in 2015, 2017-2018; thereby impacting abundance and biomass estimates of this species. In 2018, biomass estimates in Div. 3L, 3N, and 3O were 28 142 t, 71 267 t, and 72 500 t (respectively). In Div. 3N, the 2018 biomass estimate was above the 2013-2017 average of 59 268 t, while that for Div. 3O was above the five-year average of 65 354 t. The 2019 biomass estimate of 147 348 t for Divs. 3NO was above the 2014-2018 average of 128 451 t; increasing since 2015. In Div. 3L, the 2018 (28 142 t) and 2019 (24 403 t) biomass estimates were above the 2013-2017 average of 21 413 t.

EU-Spain 3NO Survey

Spain initiated a stratified-random survey in the NRA of Divs. 3NO in 1995. Initially, this survey was carried out in spring with the *C/V Playa de Menduïña* using a Pedreira bottom trawl. Since 2001, the *R/V Vizconde de Eza* replaced that research vessel, and a Campelen trawl replaced Pedreira gear (González-Troncoso *et al.* 2020). Abundance and biomass of Thorny Skate were estimated from EU-Spain surveys in the NRA of Divs. 3NO from 1997-2019. Although the EU-Spain biomass index indicated an increase in 2012, it appears to be following a declining trend since 2006 from 55 810 t to its lowest estimate of 2 758 t in 2019.

A comparison of the Canadian Campelen spring 3NO biomass indices to those of the Spanish Divs. 3NO surveys in 1997-2019 indicated that the trends have diverged since 2007: the EU-Spain index declined until 2011, while the Canadian index has followed a generally increasing trend (Fig. 6). It should be noted that the Canadian spring survey covers the entire area of Divs. 3NO, whereas the Spanish survey is limited to the NRA of Divs. 3NO.

EU-Spain 3L Survey

Spain initiated a stratified-random summer bottom trawl survey in the NRA of Div. 3L in 2003. This survey was conducted with the *R/V Vizconde de Eza* using a Campelen trawl. Due to the vessel's mechanical difficulties, the survey was not conducted in 2005, and some strata were missed in 2003-2004 (Román-Marcote *et al.* 2020). Abundance and biomass estimates of Thorny Skate were available from EU-Spain surveys in the NRA of Div. 3L from 2003-2019 (excluding 2005).

A comparison of the Spanish Div. 3L biomass and Canadian spring Div. 3L indices in 2003-2019 indicated generally similar patterns until 2014 when they diverged: the EU-Spain index followed an increasing trend to 2015 (Fig. 7). The EU-Spain index has since declined from 18 753 t to its lowest values in 2018 (7 479 t) and 2019 (7 820 t). The Canadian Campelen Div. 3L fall biomass indices reflected a pattern similar to that from the Spanish survey until 2016, when they diverged: the EU-Spain index followed the declining trend, while Canadian biomass estimates continued along a gradually increasing trend from 3 660 t to 5 302 t. It should be noted that the Canadian surveys cover the entire area of Div. 3L, whereas the Spanish survey is limited to the NRA of Div. 3L.

Index of Fishing Mortality

A relative Fishing Mortality Index (Relative F=STACFIS-agreed commercial landings/Canadian spring survey biomass) was calculated for Thorny Skate in Divs. 3LNO and Subdiv. 3Ps for 1996-2019. Relative F for Divs. 3LNO increased from the late 1980s to a peak of 32% in 1997, then decreased and remained stable at approximately 17% during 1998-2004 (Fig. 8). In 2005-2011, this Divs. 3LNO index averaged 6%, then remained around 4% since 2012. Since 2010, relative fishing mortality in Subdiv. 3Ps was $\leq 2\%$.

Survey Catch Composition – Other Skates

Canadian spring survey catches of skates in Divs. 3LNOPs over 1996-2019 were dominated by Thorny Skate: comprising 97-99% (Fig. 9). The remaining 2-3% of skates were mainly Smooth Skate (*Malacoraja senta*) and Spinytail Skate (*Bathyraja spinicauda*), with lesser amounts of Winter Skate (*Leucoraja ocellata*), Jensen's Skate (*Amblyraja jenseni*), Round Skate (*Rajella fyllae*), Barndoor Skate (*Dipturus laevis*), and Soft Skate (*Malacoraja spinacidermis*). The Smooth Skate spring biomass index was highest in 2009, then followed a declining trend to 2019 (Fig. 10). Although highly variable, Spinytail Skate spring biomass has been increasing since 2003; while Winter Skate appeared generally in decline since then. The Round Skate spring biomass index was also highly variable, but at very low levels (except for high estimates in 2010, 2018). The remaining skate species were occasionally caught by the Canadian Campelen trawl.

The Canadian fall survey of Divs. 3LNO in 1995-2019 consistently caught Smooth Skate, Spinytail Skate, and Round Skate; with biomass estimates fluctuating throughout this period (Fig. 10). In addition to the skate species caught in spring surveys, Bigelow's Skate (*Rajella bigelowi*) was captured occasionally at low levels in fall surveys.

Survey Size Structure

Lengths of Thorny Skates caught in Canadian Campelen spring surveys of Divs. 3LNO and Subdiv. 3Ps in 2008-2019 ranged from 7-105 cm TL (Fig. 11). For most areas and years, a peak of young-of-the-year skates (YOY: 7-21 cm TL) was observed, and averaged 15 cm. In 2008-2017, modes between 65-77 cm were usually found, with a few years also indicating modes within 23-28 cm. Similarly, the 2018 and 2019 spring surveys showed modes between 66-79 cm, and also 33-36 cm, while a 50-cm peak was seen in 2018. The Canadian Campelen fall surveys of Divs. 3LNO in 2008-2019 caught Thorny Skates from 9-105 cm TL (Fig. 12). Peaks of YOY skates were also found in most years, averaging 14-15 cm. Also notable were two dominant peaks at 44 cm and 70 cm in 2010. Although larger Thorny Skates (82-92 cm) were similar in all years, they were absent in 2014 while numbers of 73-81 cm skates were greatly reduced due to the lack of a fall survey in Divs. 3NO.

Lengths of Thorny Skate caught in the EU-Spain 3NO survey during 1997-2019 ranged from 11-104 cm. There has been no recruitment visible in many years (González-Costas *et al.* 2020). In the EU-Spain 3L survey over 2006-2019, Román-Marcote *et al.* (2020) reported a 10-95 cm range of Thorny Skates. In 2018-2019, they observed modes between 32-40 cm, and 62-76 cm; similar to the Canadian spring surveys.

Recruitment

A standardized index of Thorny Skate recruitment, based on the number of skates ≤ 21 cm TL, is illustrated in Figure 13. This recruitment index declined from 1.5 in 1996 to below the 1996-2019 average, with the lowest value in 1999 and 2004. Although this index remained above 1.0 over 2010-2013, it was followed by a steep decline to in 2014-2015. The recruitment index increased in 2016-2017, then dropped below average in 2018. In 2019, the recruitment index was at a level comparable to the long-term average. The 2006 index is not presented, because Canadian survey coverage was incomplete over that spring, and the Div. 3L survey was incomplete in 2015 and 2017.

Distribution

In Divs. 3LNO and Subdiv. 3Ps, the distribution of Thorny Skate has changed significantly since the 1980s. In the early 1980s, Thorny Skates were widely distributed over the entire Grand Banks in moderate to high concentrations (Kulka and Miri 2007). By the late 1990s, much of the biomass was concentrated in the southwest. In 2001-2005, the area of high concentration expanded northward and along the Bank edge. It is important to note that part of this population moves to the shelf edge in spring, thereby moving outside of the Canadian spring survey area; they are concentrated on the shelf during the fall (Kulka *et al.* 2004). In 2010-2019, Thorny Skate distribution in Divs. 3LNOPs continued to be concentrated on the southwestern Grand Banks, in Subdiv. 3Ps, and northward along the edge of the Bank in the spring survey (Fig. 14a,b). Strata-biomass plots for 2008-2019 show the expansion of skate biomass along the southwestern slopes and into Subdiv. 3Ps (Fig. 15a,b). In the Canadian fall survey over 2010-2019, Thorny Skate continued to be concentrated along the shelf edge; although higher densities were also apparent on the Grand Banks (Fig. 16a,b).

Summary

Thorny Skate underwent a decline in Divs. 3LNO over the late 1980s, suddenly increased in 1990-1991, declined again over 1992-1996, then stabilized at a low level (except for a slight increase in 2007-2008). Thorny Skate distribution in Divs. 3LNOPs for 2010-2019 continued to be concentrated on the southwestern Grand Banks, in Subdiv. 3Ps, and northward along the edge of the Bank. An Index of Fishing Mortality for Divs. 3LNO increased from the late 1980s to a peak of 32% in 1997, then stabilized at approximately 17% during 1998-2004. In 2005-2011, this Index averaged 6%, and remained around 4% since 2012. From a peak of 18 277 tons in 2000, total reported landings of skate by all countries in Divs. 3LNO declined to an average of 5 357 t in 2005-2011. In 2012-2018, average reported landings from Divs. 3LNO further declined to 3 805 t. In 2019, STACFIS-agreed landings totaled 3 697 t. The 2020 TAC of 7 000 t for skates in the NRA of Divs. 3LNO continues to exceed the average commercial catch during a period when minimal or no rebuilding of this stock has occurred.

Acknowledgments

We thank Fisheries and Oceans Canada staff, who participated in Canadian research surveys, Canadian At-Sea Fisheries Observers, who collected data and specimens aboard commercial vessels under adverse conditions over many years, and the Instituto Español de Oceanografía in Vigo (Spain) for data from Spanish research surveys of Divs. 3LNO (in the NRA); thereby allowing us to estimate trends and examine various biological aspects of Thorny Skate.

Table 3a. Abundance of Thorny Skate from Canadian spring research surveys in Divs. 3LNOPs, 1984-2019. Surveys were conducted with an Engel trawl (1984-spring 1995; converted to Campelen-equivalents), and a Campelen trawl (spring 1996-2019). The deeper (>103 m) portion of Divs. 3NO, as well as Subdiv. 3Ps, were not surveyed in 2006; and Div. 3L was not completely surveyed in 2015 and 2017.

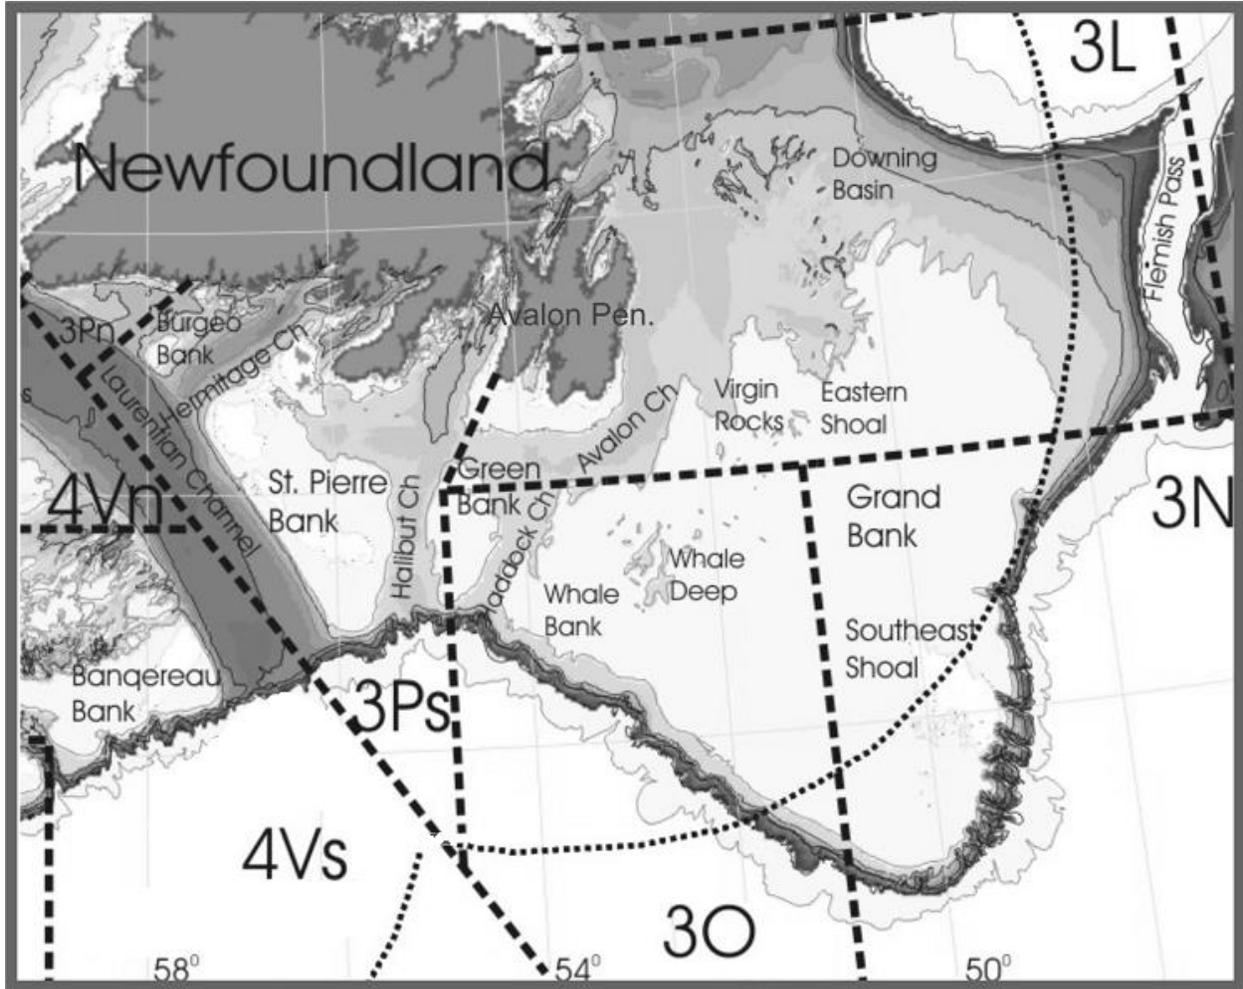

Figure 1. Map of NAFO Divisions 3LNO and Subdivision 3Ps (thick black dashed lines) in relation to Canada's Exclusive Economic Zone (thin black dotted curve).

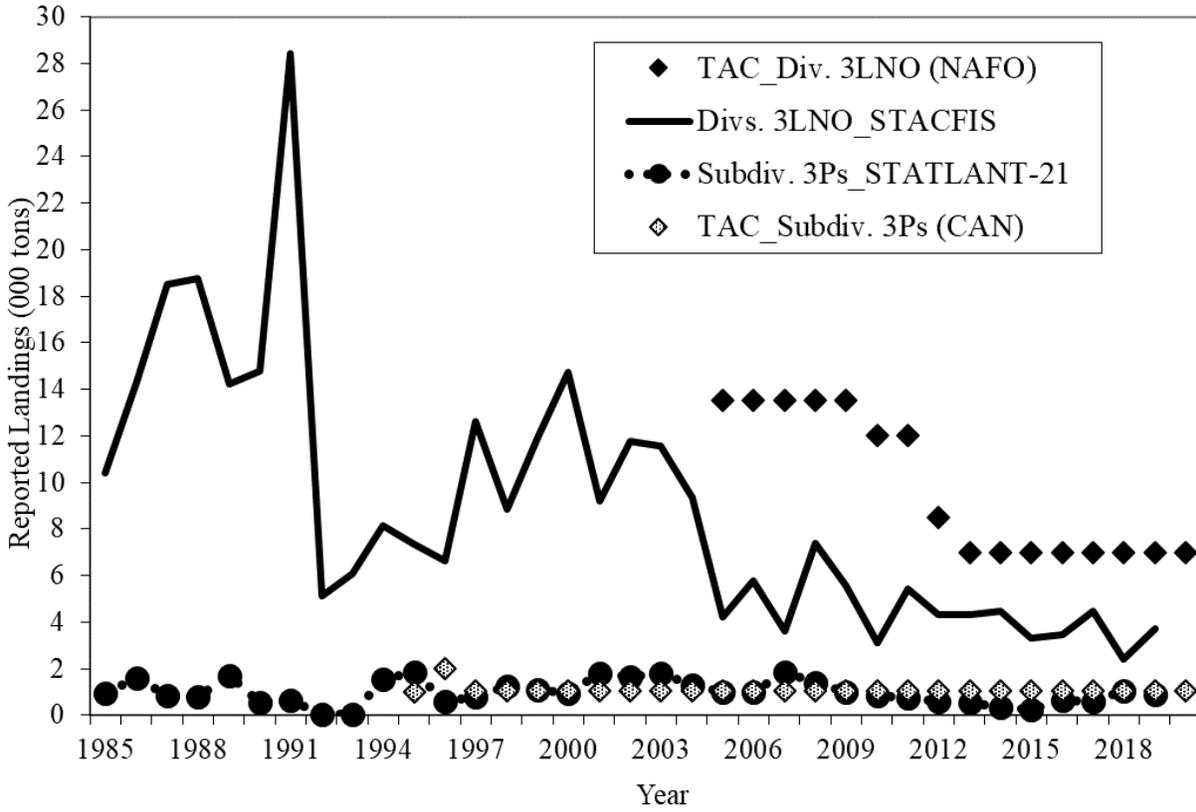

Figure 2. Total reported landings and Total Allowable Catch (TAC) of Thorny Skate in Divs. 3LNO (STACFIS) and Subdiv. 3Ps (STATLANT-21A), 1985-2019.

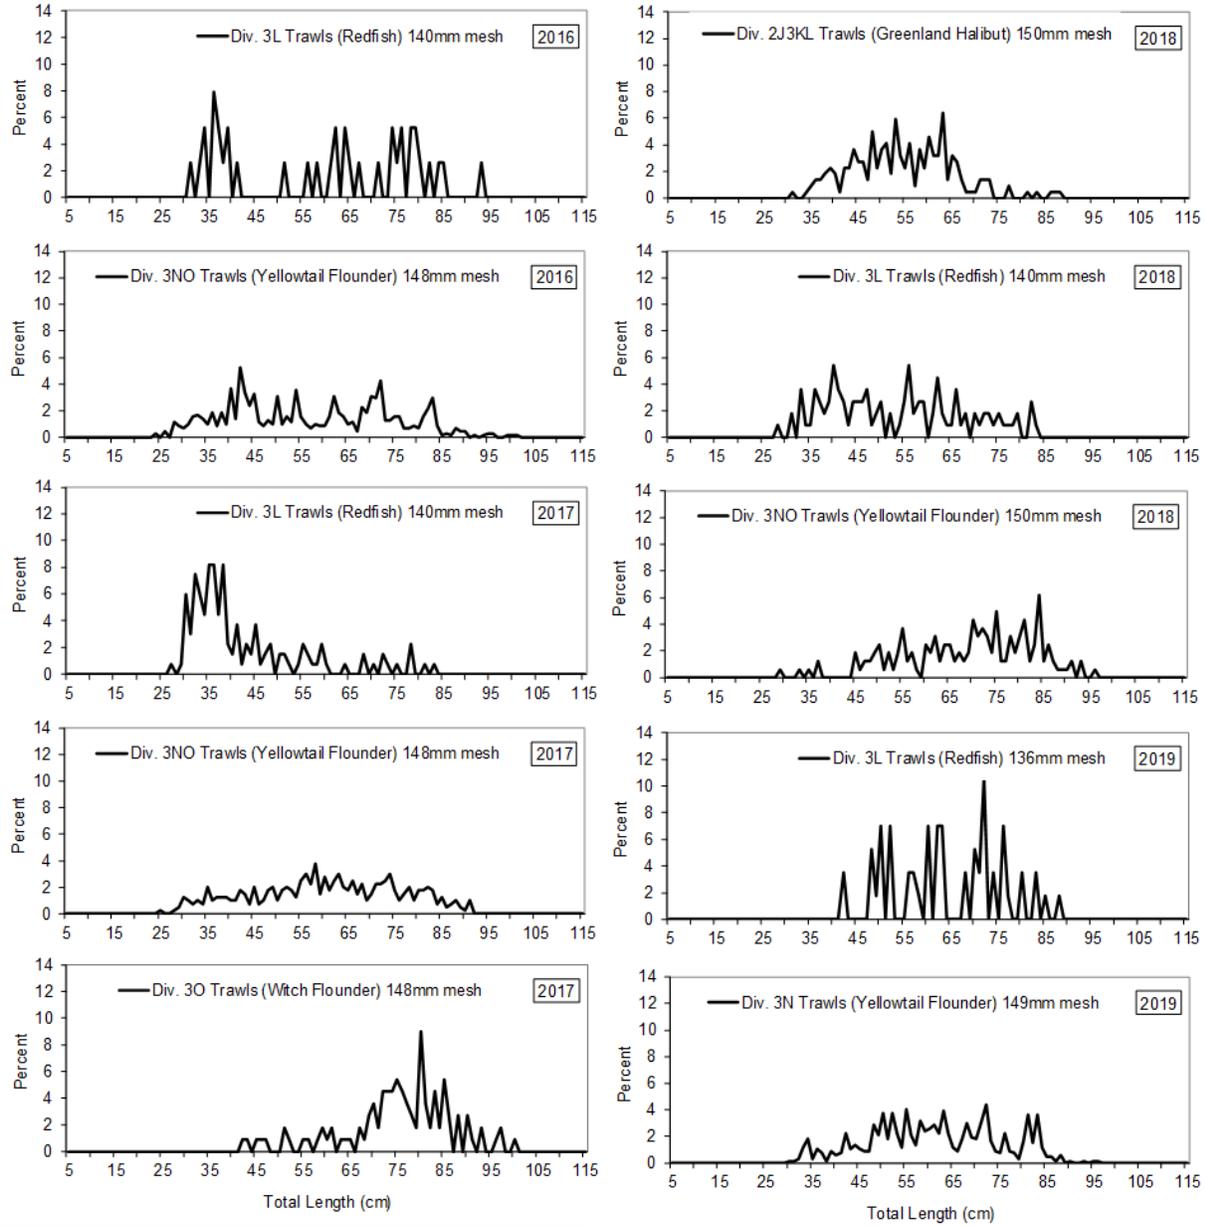

Figure 3a. Length distributions of Canadian commercial catches (sexes combined) in Subareas 2+3 from skate bycatch fisheries, 2016-2019. Note the Y-axis for Shrimp in 2018 is almost double the value of all others. Data are from Canadian At-Sea Fisheries Observers, and include discards.

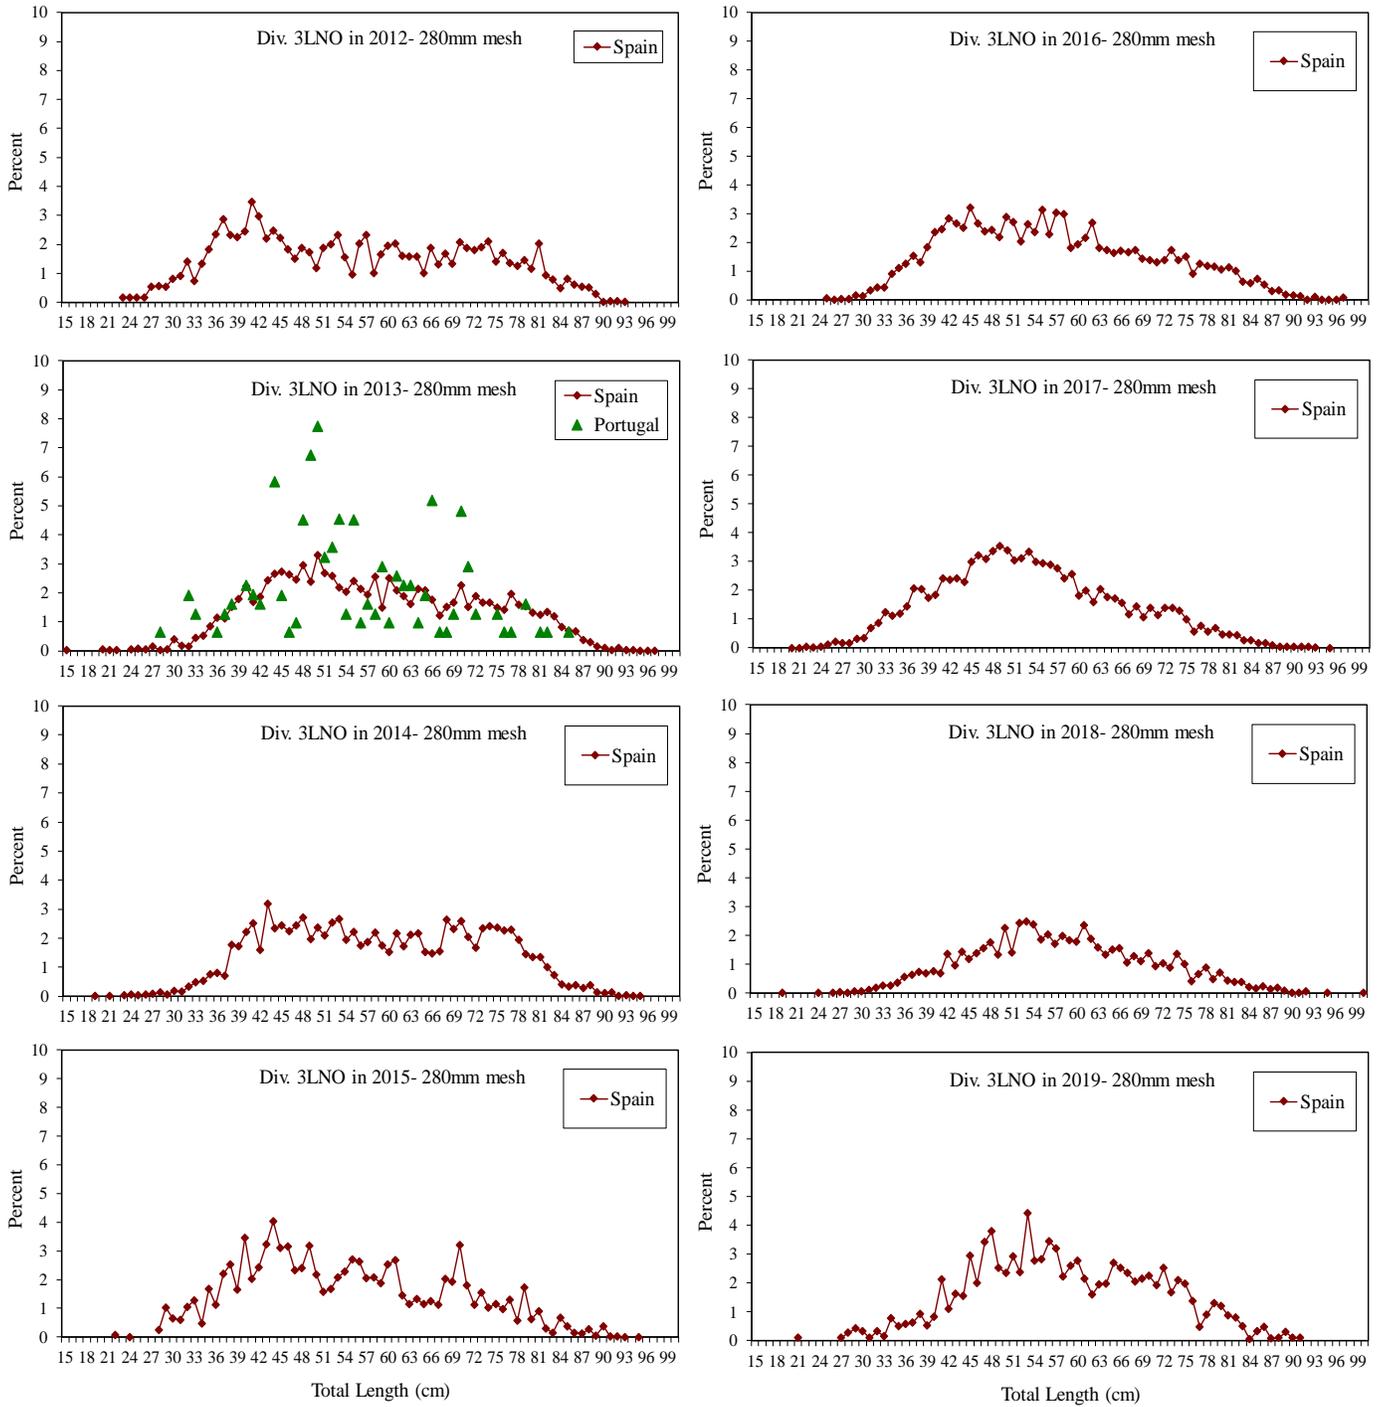

Figure 3b. Length distributions of commercial catches (sexes combined) in Divs. 3LNO by country for the skate-directed (280 mm) trawl fishery, 2012-2019.

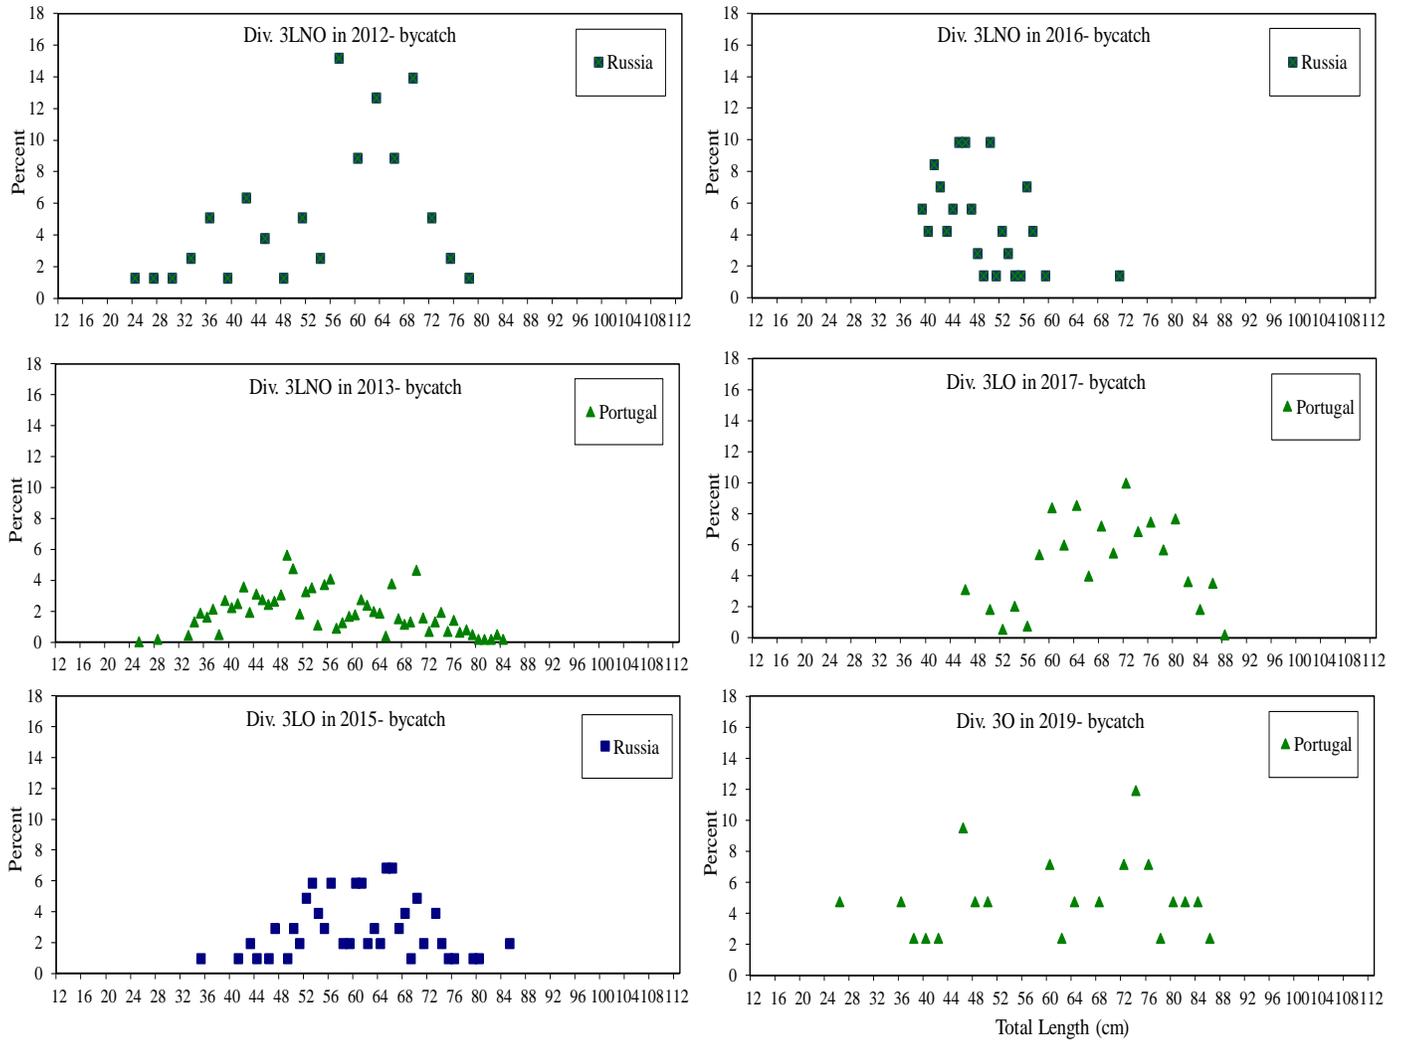

Figure 3c. Length distributions of commercial catches (sexes combined) in Divs. 3LNO by country for skate bycatch (130-135 mm) trawl fisheries in 2012-2013, 2015-2017, and 2019.

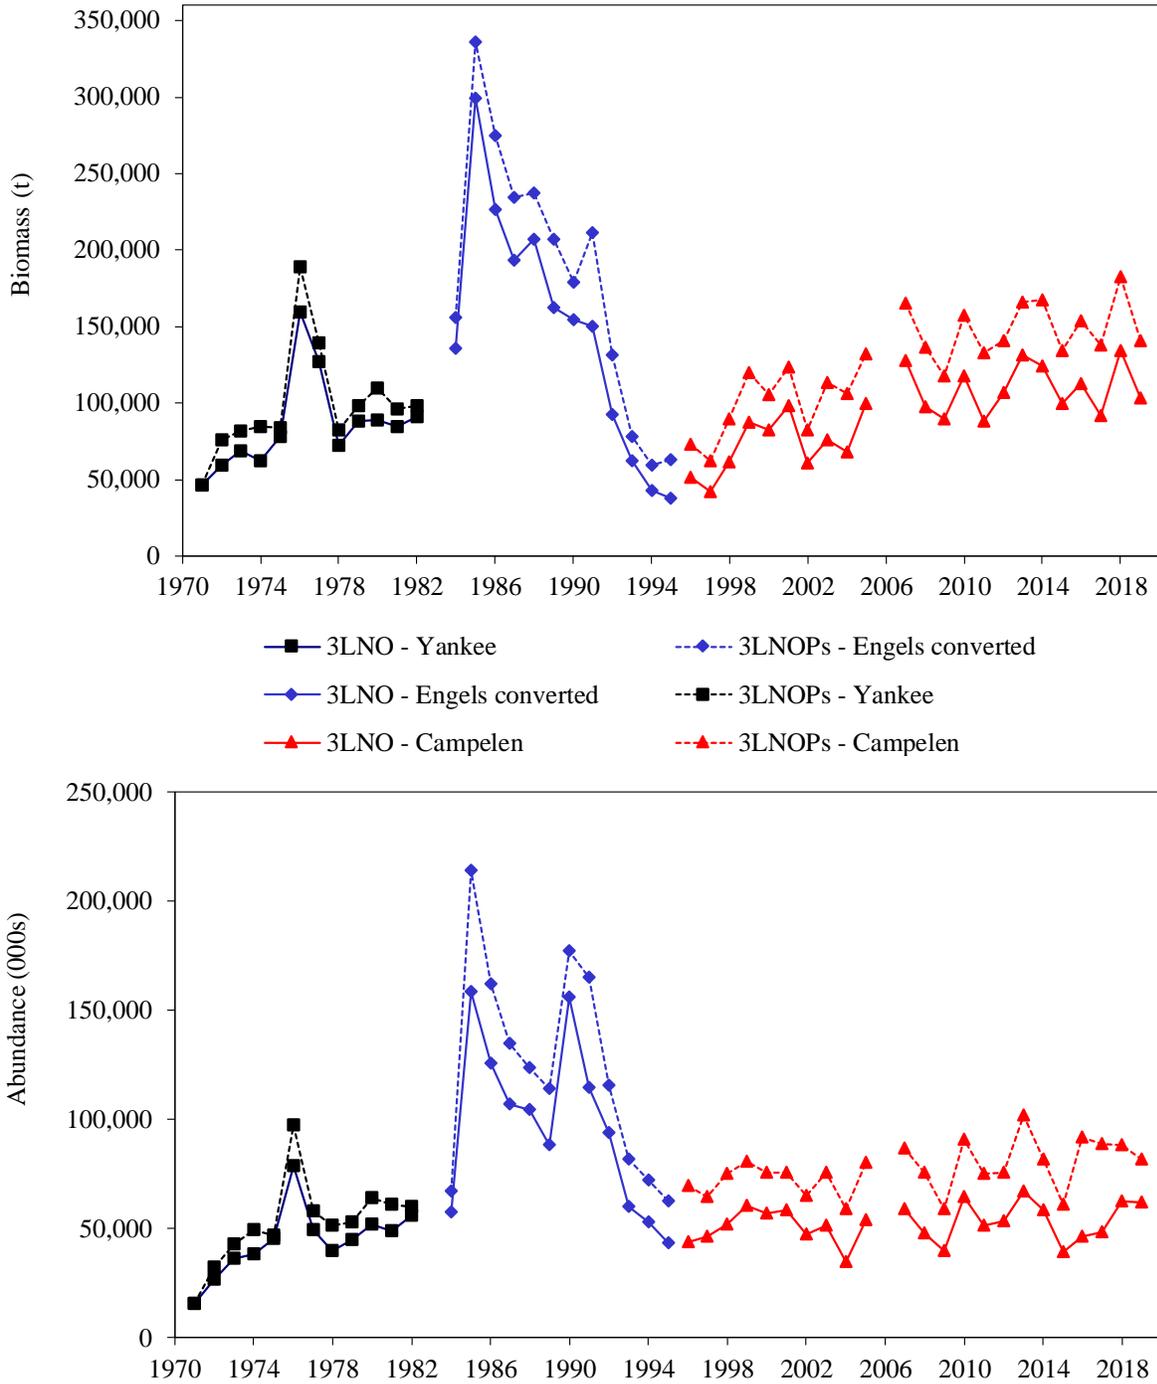

Figure 4a. Relative biomass and abundance indices for Thorny Skate from Canadian spring research surveys in NAFO Divs. 3LNO and 3LNOPs, 1971-2019. Divs. 3LNO were not surveyed in 1983; the deeper (>103 m) portion of Divs. 3NO, as well as Subdiv. 3Ps, were not surveyed in 2006; and Div. 3L was not completely surveyed in 2015 and 2017.

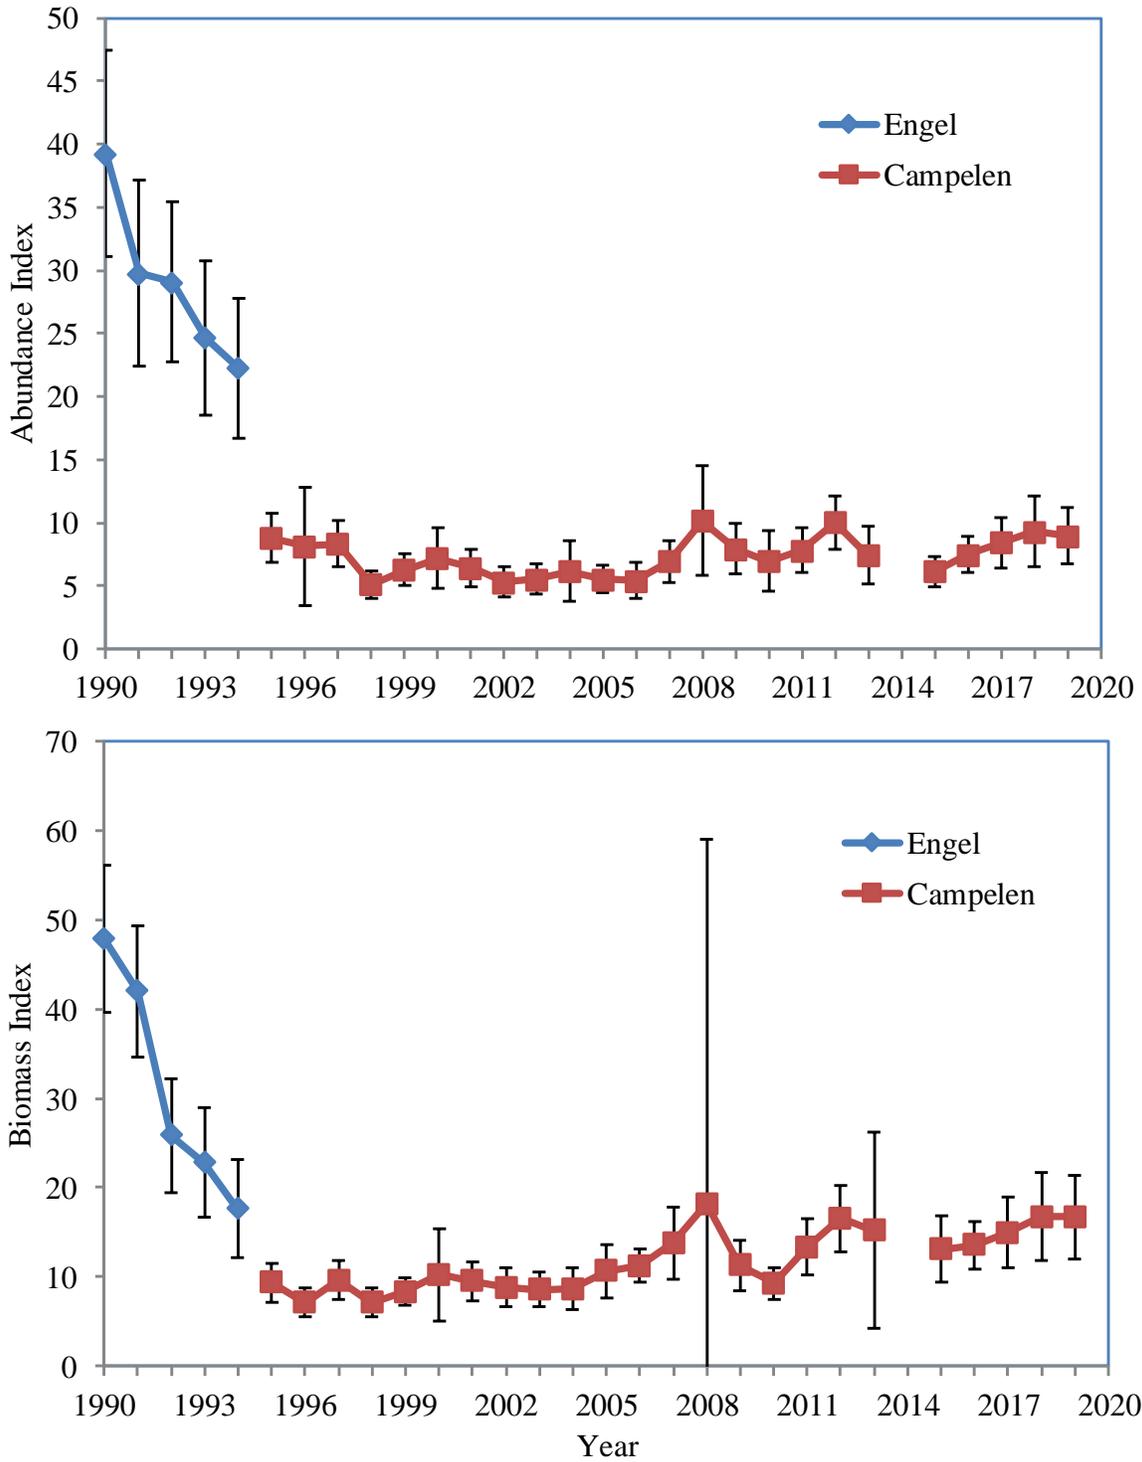

Figure 4b. Canadian fall research survey biomass and abundance indices for Thorny Skate in NAFO Divs. 3LNO, 1990-2019. Deep strata of Divs. 3NO were not surveyed in 2003, 2004, 2006, 2008; both Divisions were not surveyed in 2014; as well as deep strata of Div. 3L in 2015, 2017-2018.

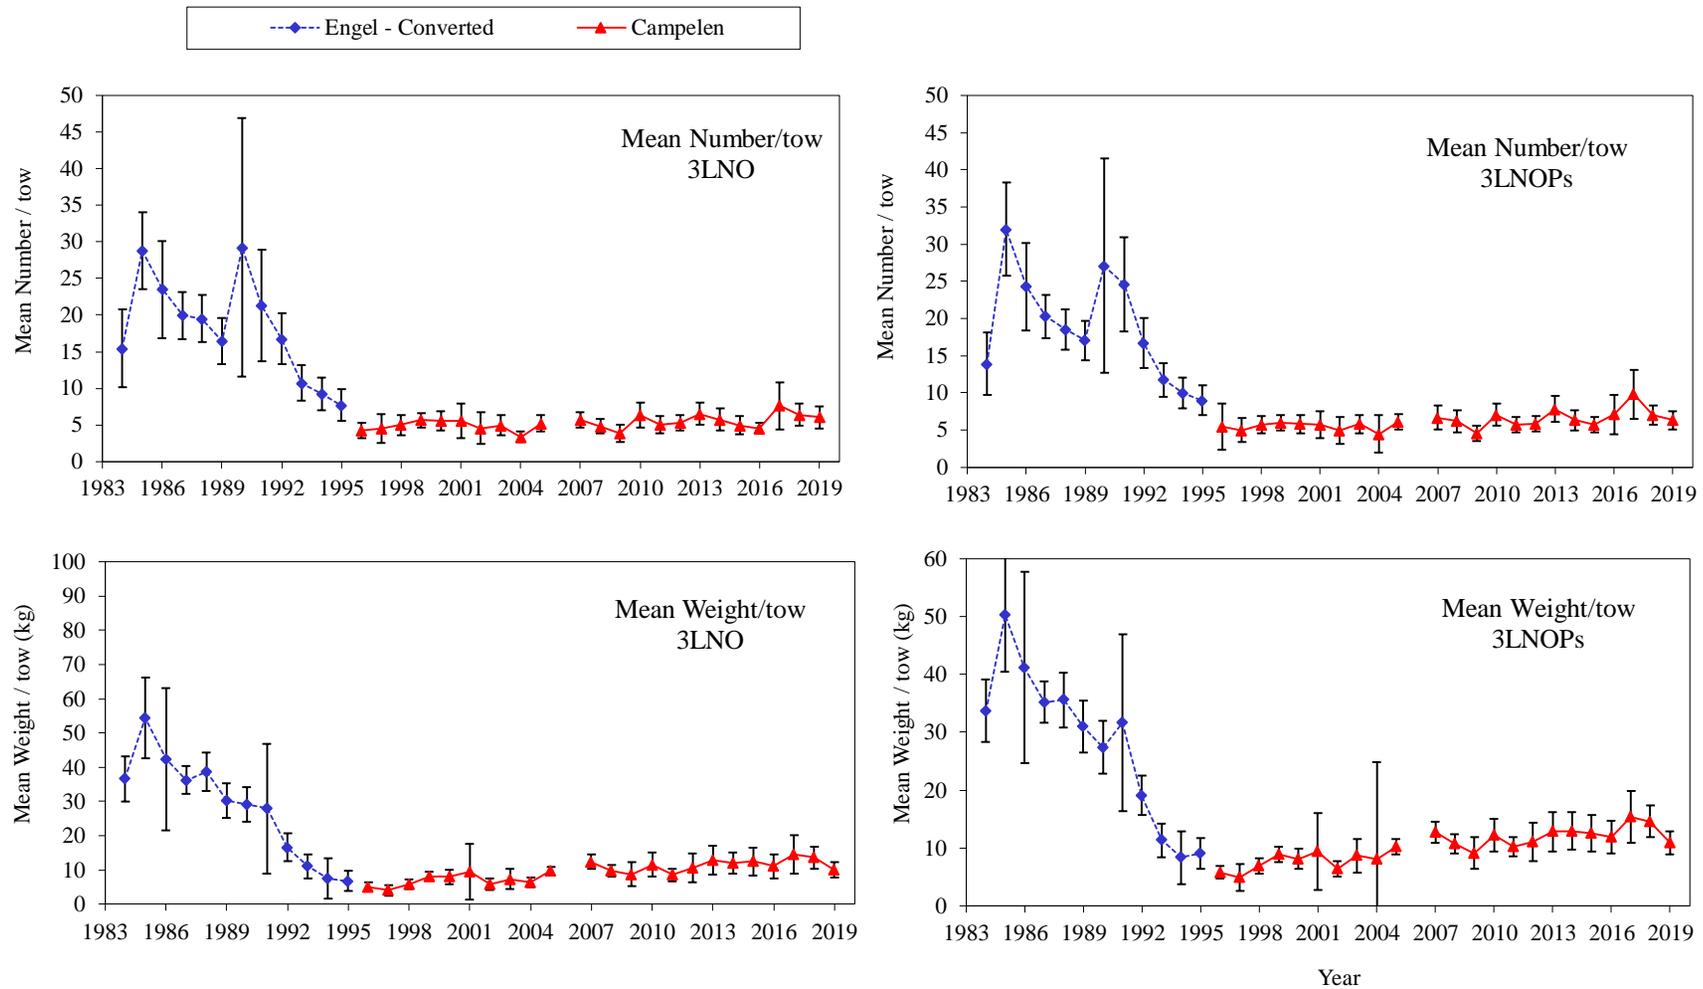

Figure 5. Mean numbers and weights (kg) per tow (+/- 95% CI) of Thorny Skate from Canadian spring surveys in NAFO Divs. 3LNO and 3LNOPs, 1983-2019. Divs. 3LNO were not surveyed in 1983; the deeper (>103 m) portion of Divs. 3NO, as well as Subdiv. 3Ps, were not surveyed in 2006; and Div. 3L was not completely surveyed in 2015 and 2017

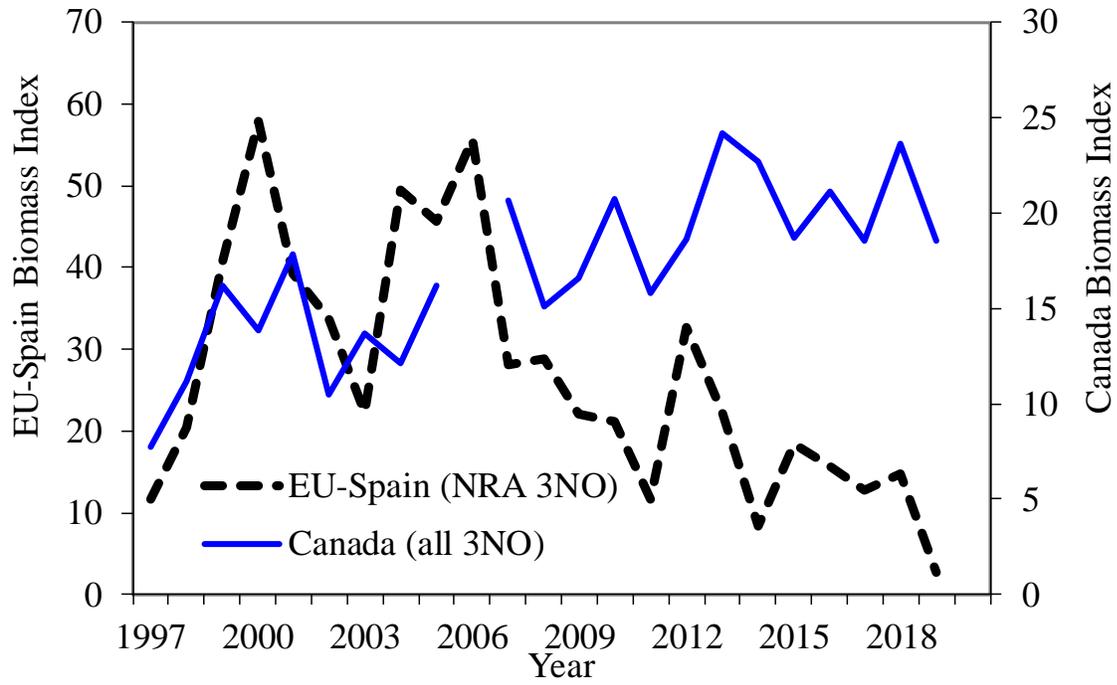

Figure 6. Comparison of Thorny Skate biomass indices from the Canadian Campelen spring survey and the Spanish spring survey in Divs. 3NO, 1997-2019. Note that Divs. 3NO were not surveyed by Canada in 2014, and Spanish surveys occur only in the NAFO Regulatory Area (NRA) of Divs. 3NO.

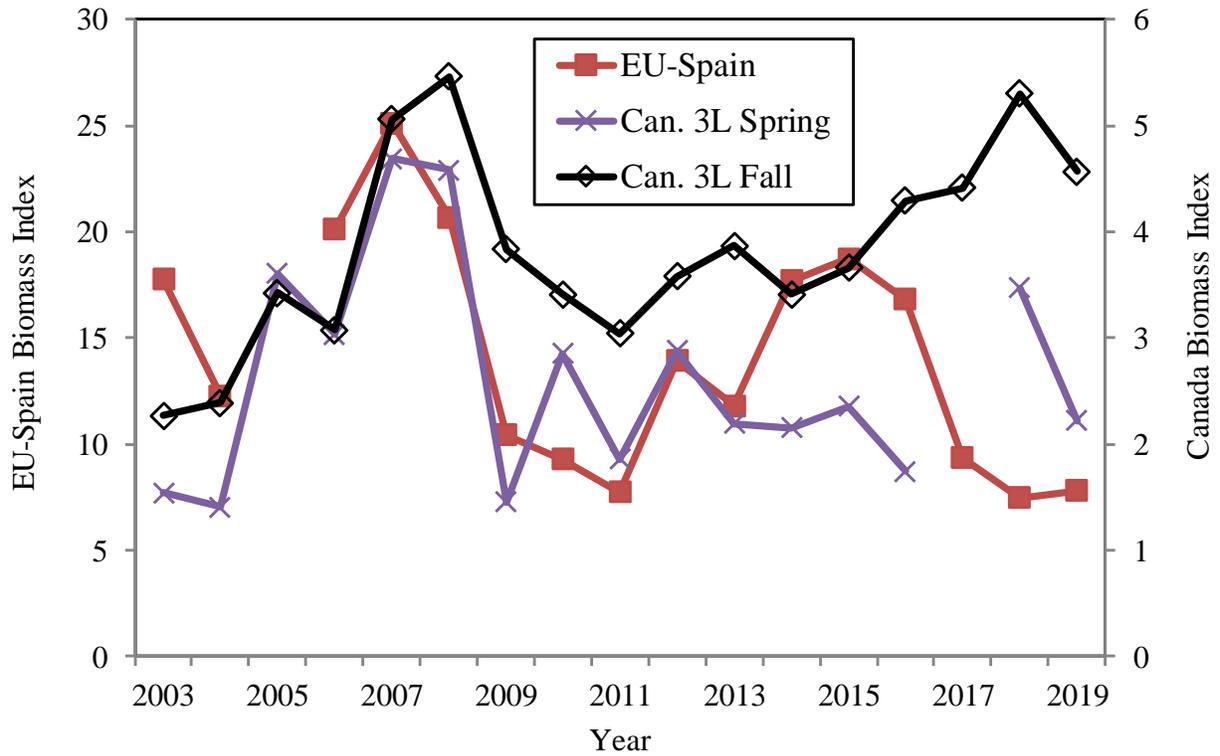

Figure 7. Comparison of Thorny Skate biomass indices from Canadian Campelen surveys and the Spanish summer survey in Div. 3L, 2003-2019. The Canadian spring survey was incomplete in 2015 and 2017; as well as Canada's fall survey of Div. 3L (deep-water) in 2015, 2017-2018; and Spanish surveys occur only in the NAFO Regulatory Area (NRA) of Div. 3L.

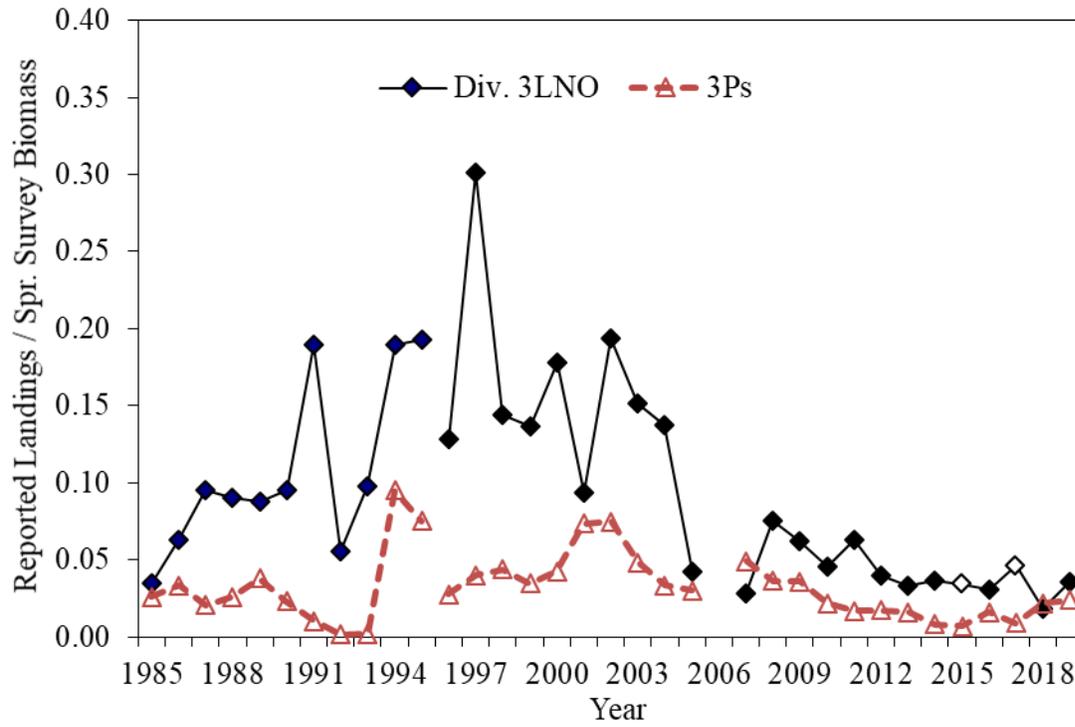

Figure 8. Fishing Mortality Index (reported landings/spring survey biomass) for Divs. 3LNO and Subdiv. 3Ps, 1985-2019. Commercial landings are STACFIS-agreed; biomass indices are from Canadian spring research surveys. The deeper (>103 m) portion of Divs. 3NO, as well as Subdiv. 3Ps, were not surveyed in 2006. The Div. 3L survey was incomplete in 2015 and 2017.

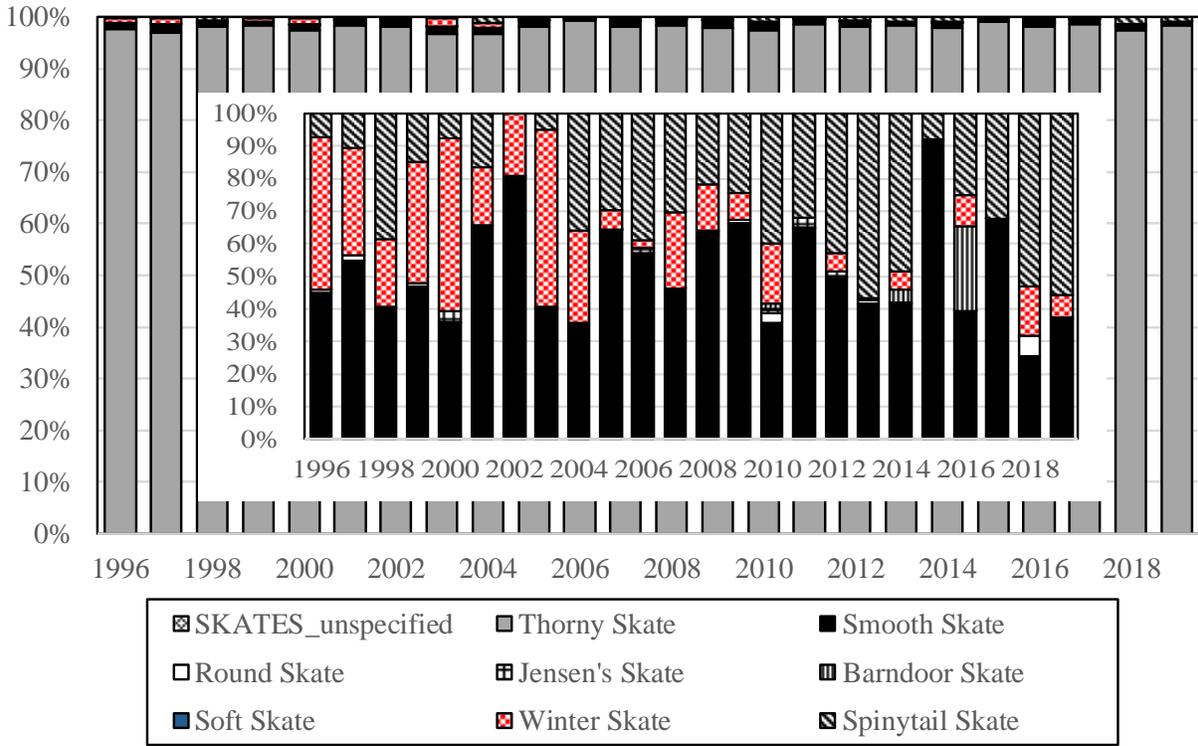

Figure 9. Percent of each skate species caught in Canadian Campelen spring surveys of Divs. 3LNOPs, 1996-2019. Note the inset graph represents proportions of species with Thorny Skate removed. In 2006, the deeper portion of Divs. 3NO, as well as Subdiv. 3Ps, were not surveyed. Div. 3L was not completely surveyed in 2015 and 2017.

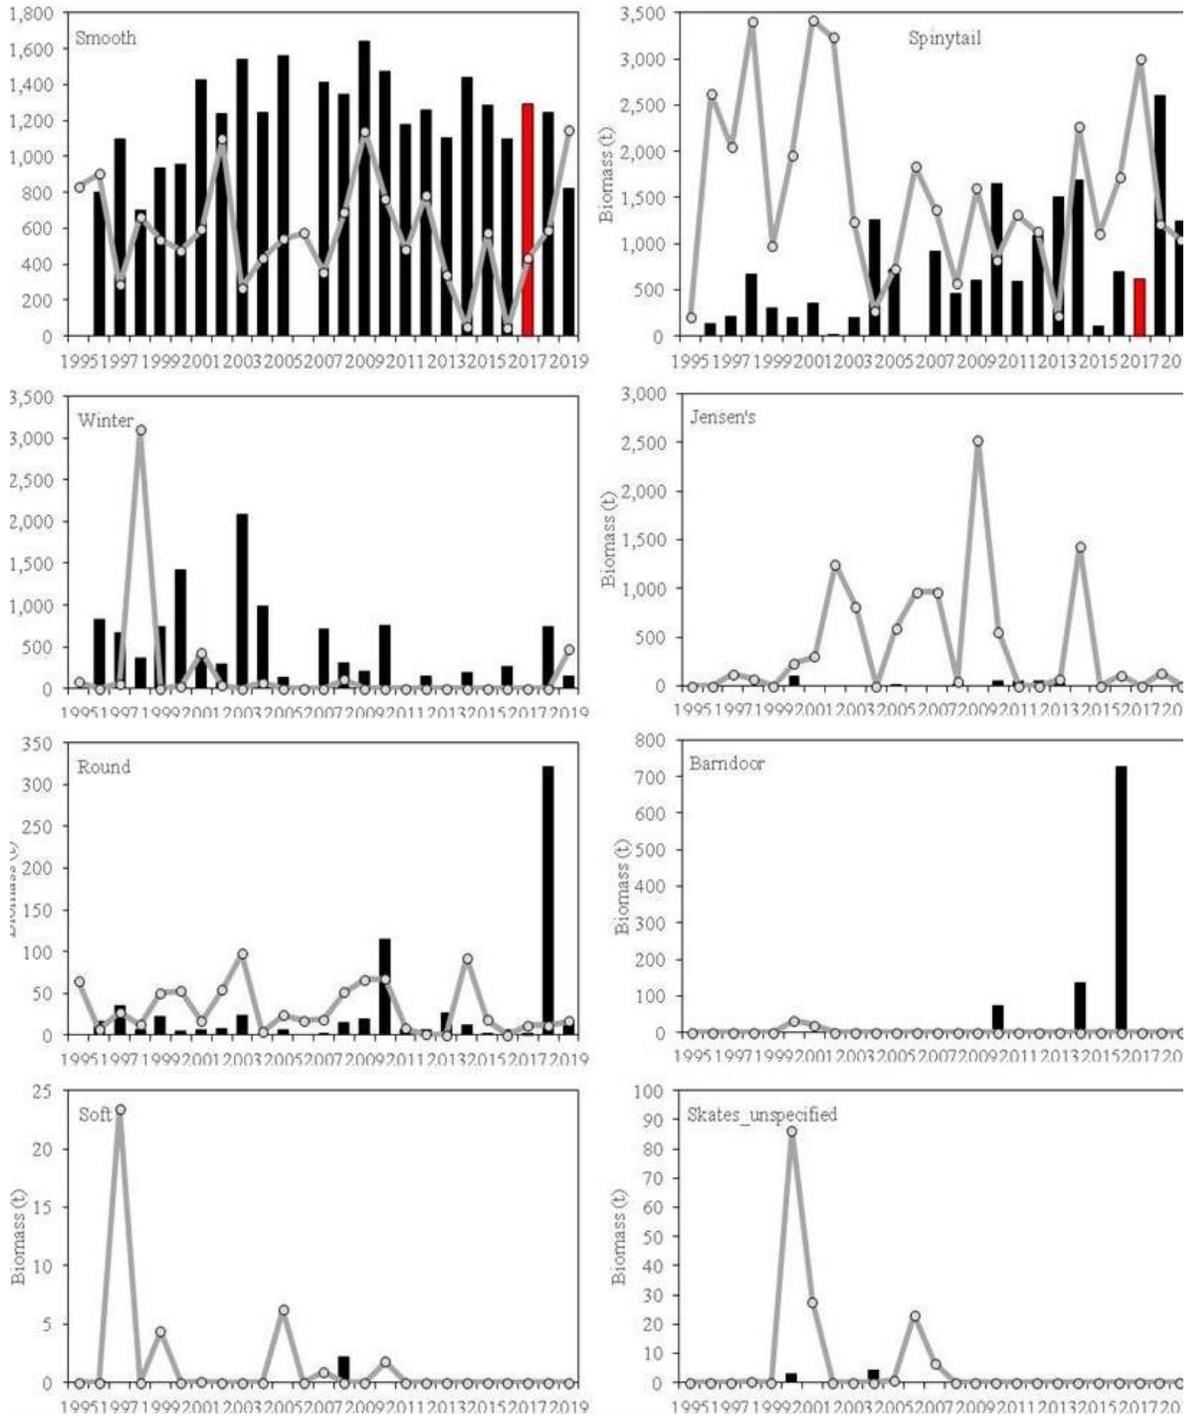

Figure 10. Biomass indices (in tons) for various skate species caught in Canadian Campelen spring surveys (black columns) of Divs. 3LNOPs in 1996-2019, and in fall surveys (gray columns) of Divs. 3LNO over 1995-2019. Spring: Subdiv. 3Ps was not surveyed in 2006; and Div. 3L was not completely surveyed in 2015, 2017. Fall: Divs. 3NO were not surveyed in 2014.

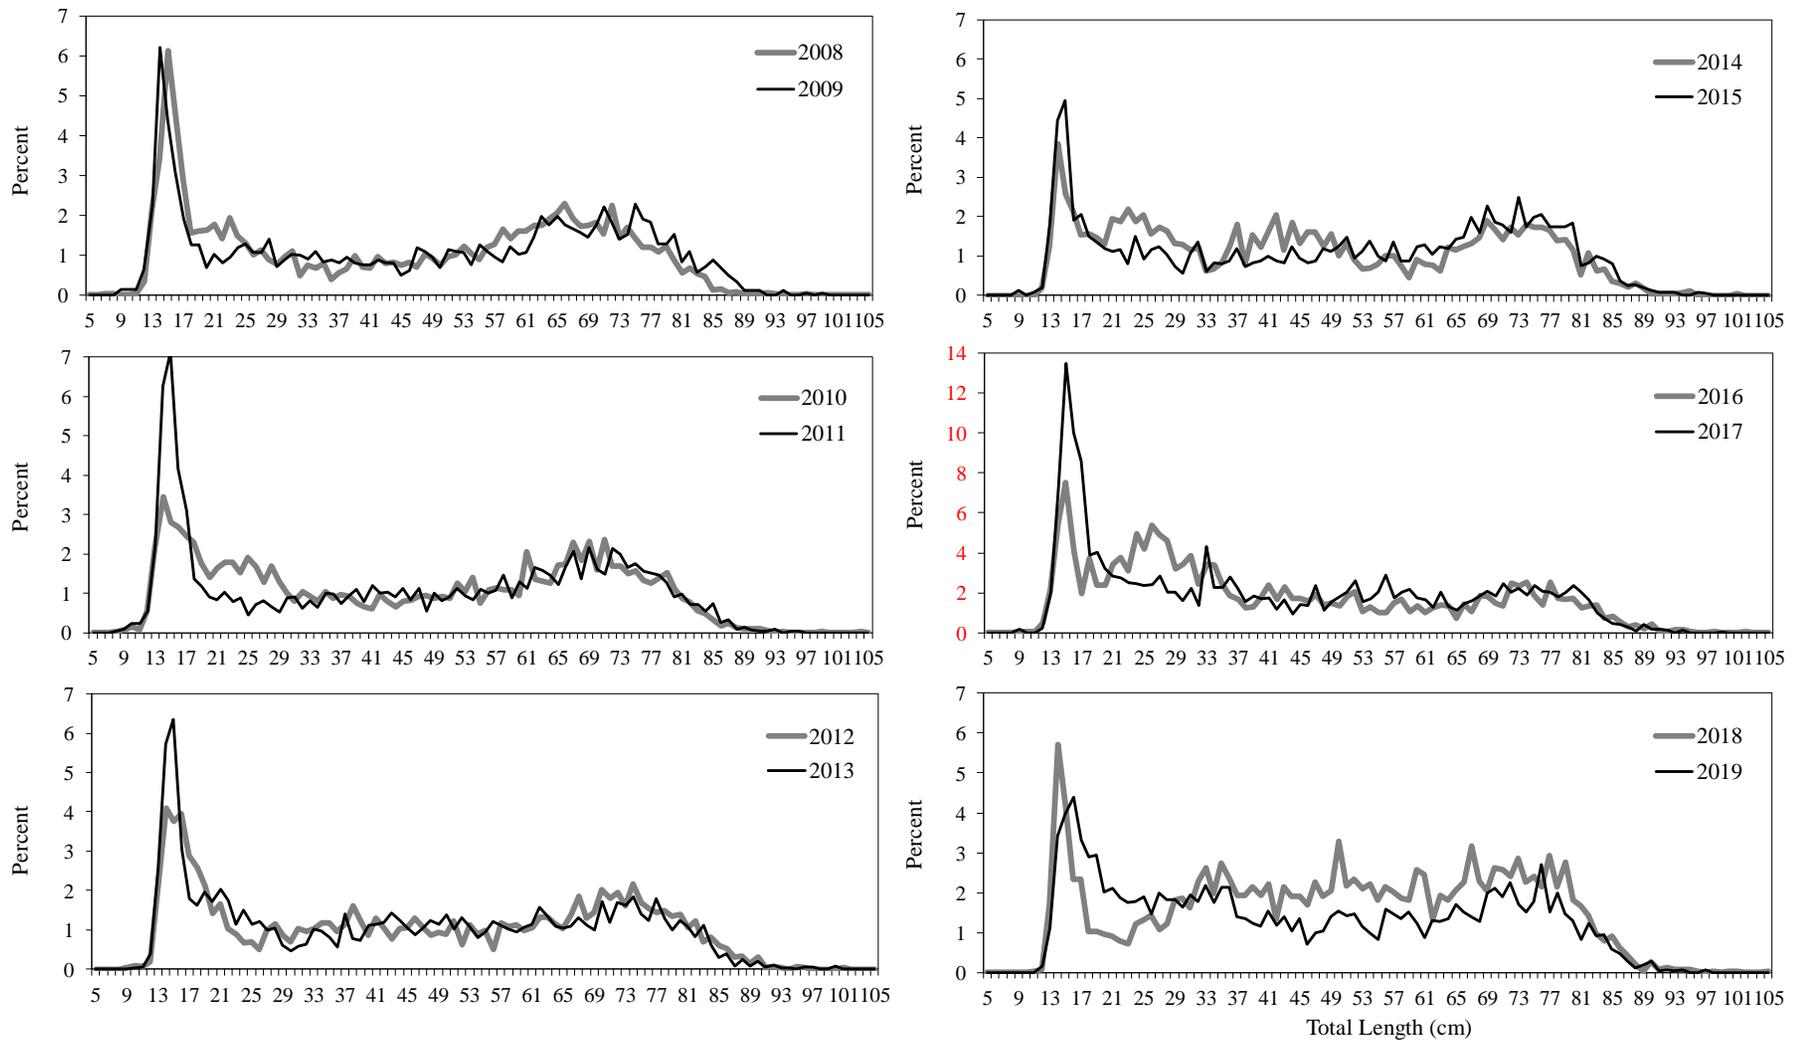

Figure 11. Length distributions of Thorny Skate from Canadian Campelen spring surveys in Divs. 3LNOPs, 2008-2019. Note the Y-axis for 2016-2017 is double the value of all others. The Div. 3L survey was incomplete in 2015 and 2017.

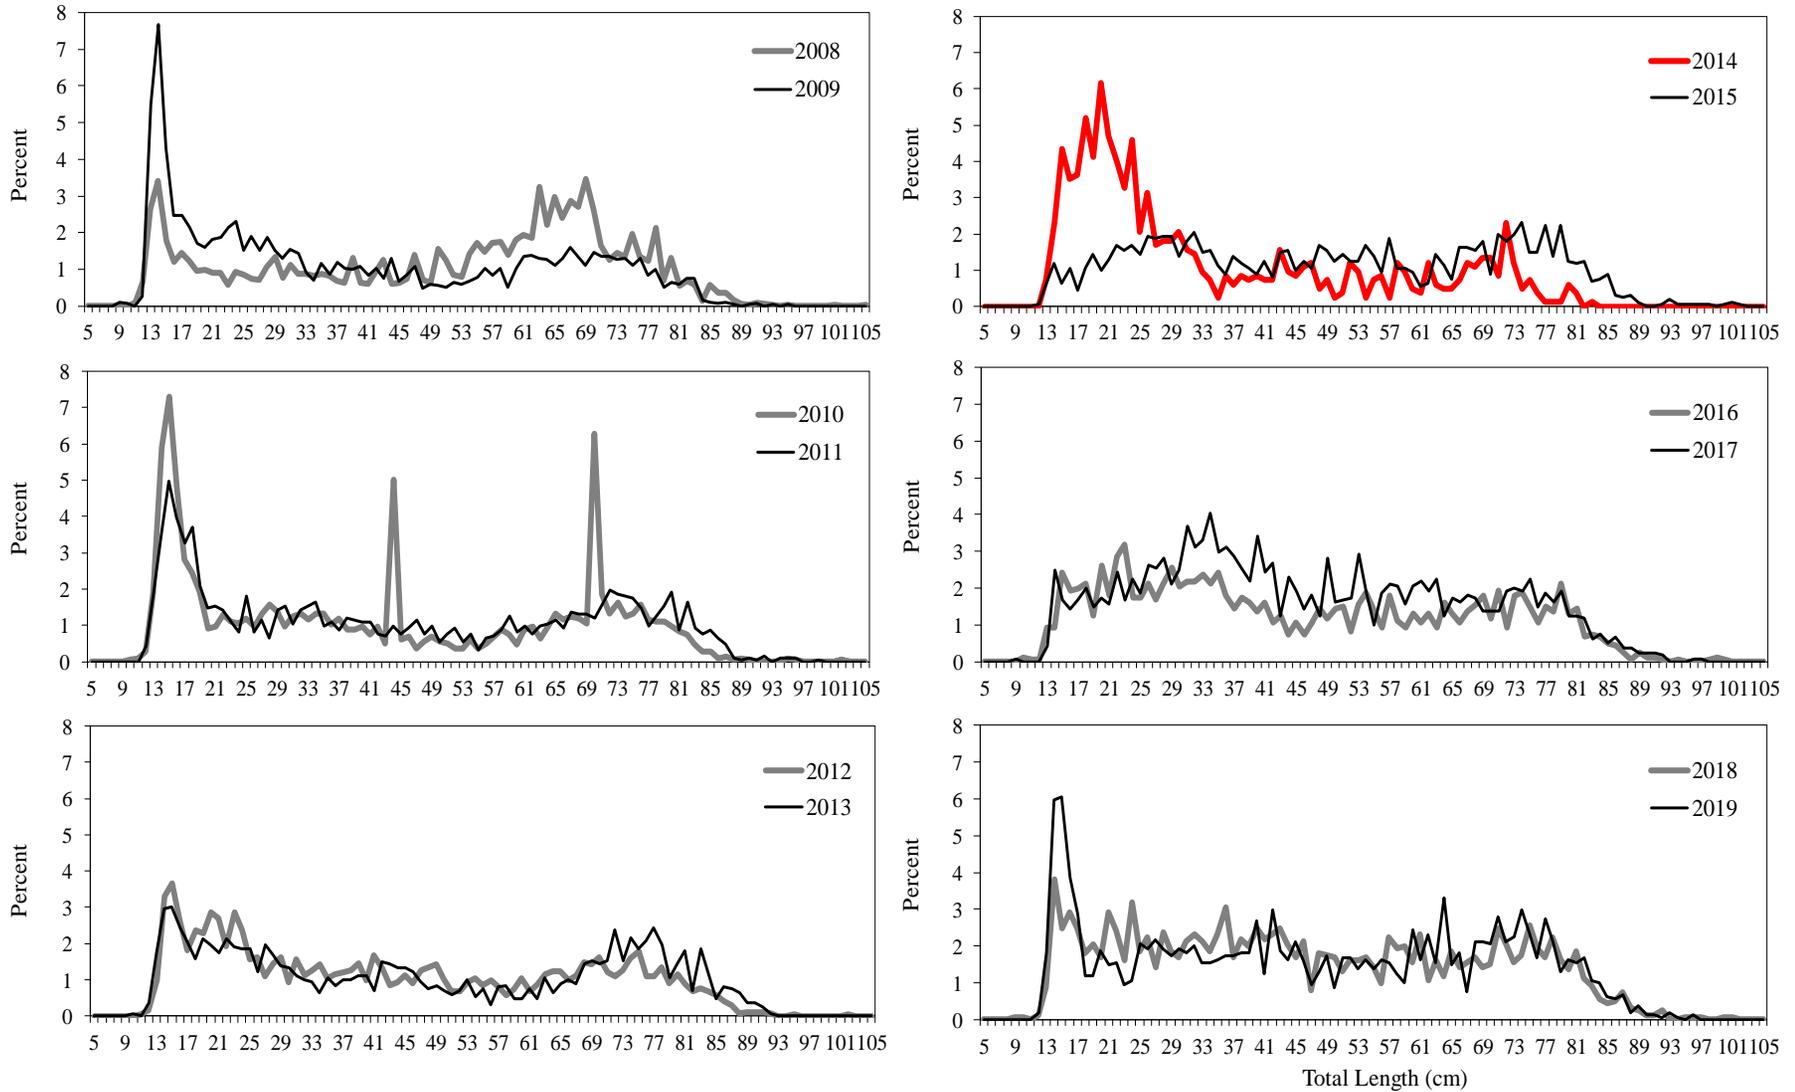

Figure 12. Length distributions of Thorny Skate from Canadian Campelen fall surveys in Divs. 3LNO, 2008-2019. Divs. 3NO were not surveyed in 2014.

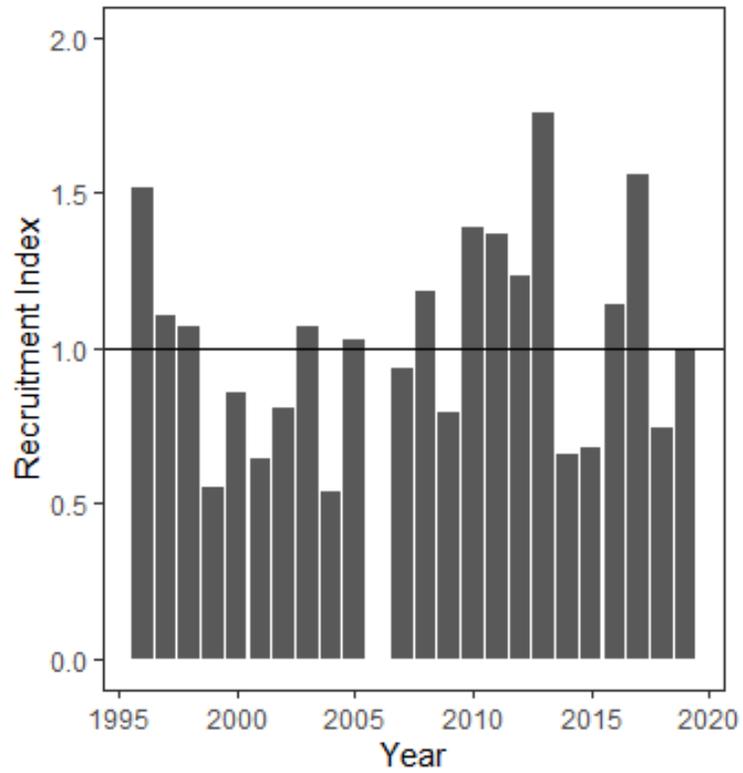

Figure 13. Standardized recruitment index (Thorny Skate ≤ 21 cm) from Canadian spring surveys in Divs. 3LNOPs, 1996-2019. The deeper portion (>103 m) of Divs. 3NO, as well as Subdiv. 3Ps, were not surveyed in 2006. The Div. 3L survey was incomplete in 2015 and 2017. The red, horizontal line depicts the standardized average recruitment for 1996-2019.

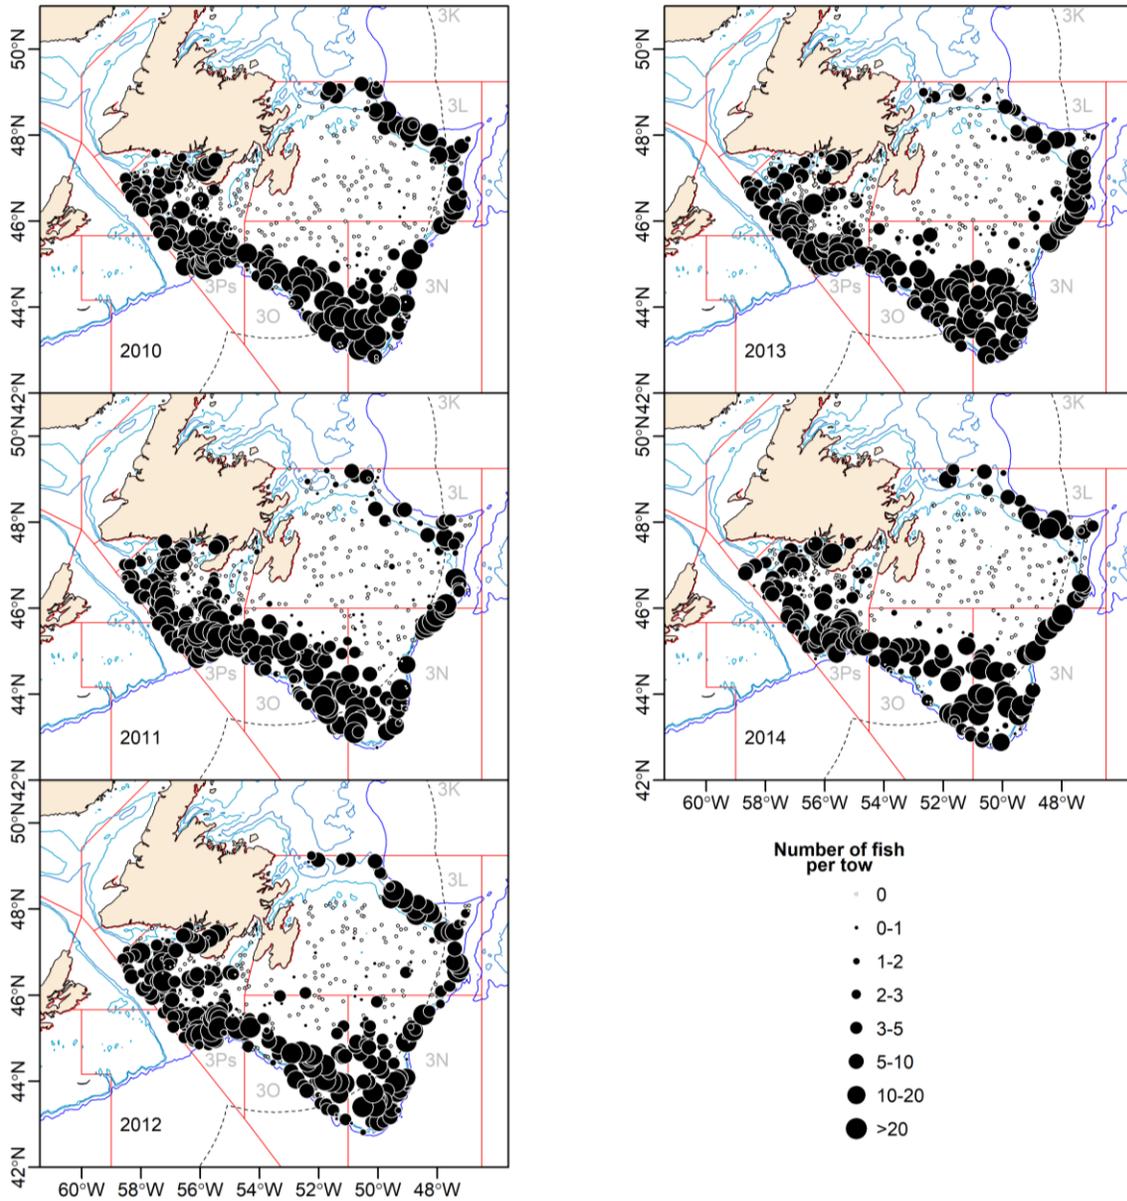

Figure 14a. Distribution (number of skates per tow) of Thorny Skate on the Grand Banks (Divs. 3LNOPs) during Canadian spring surveys, 2010-2014.

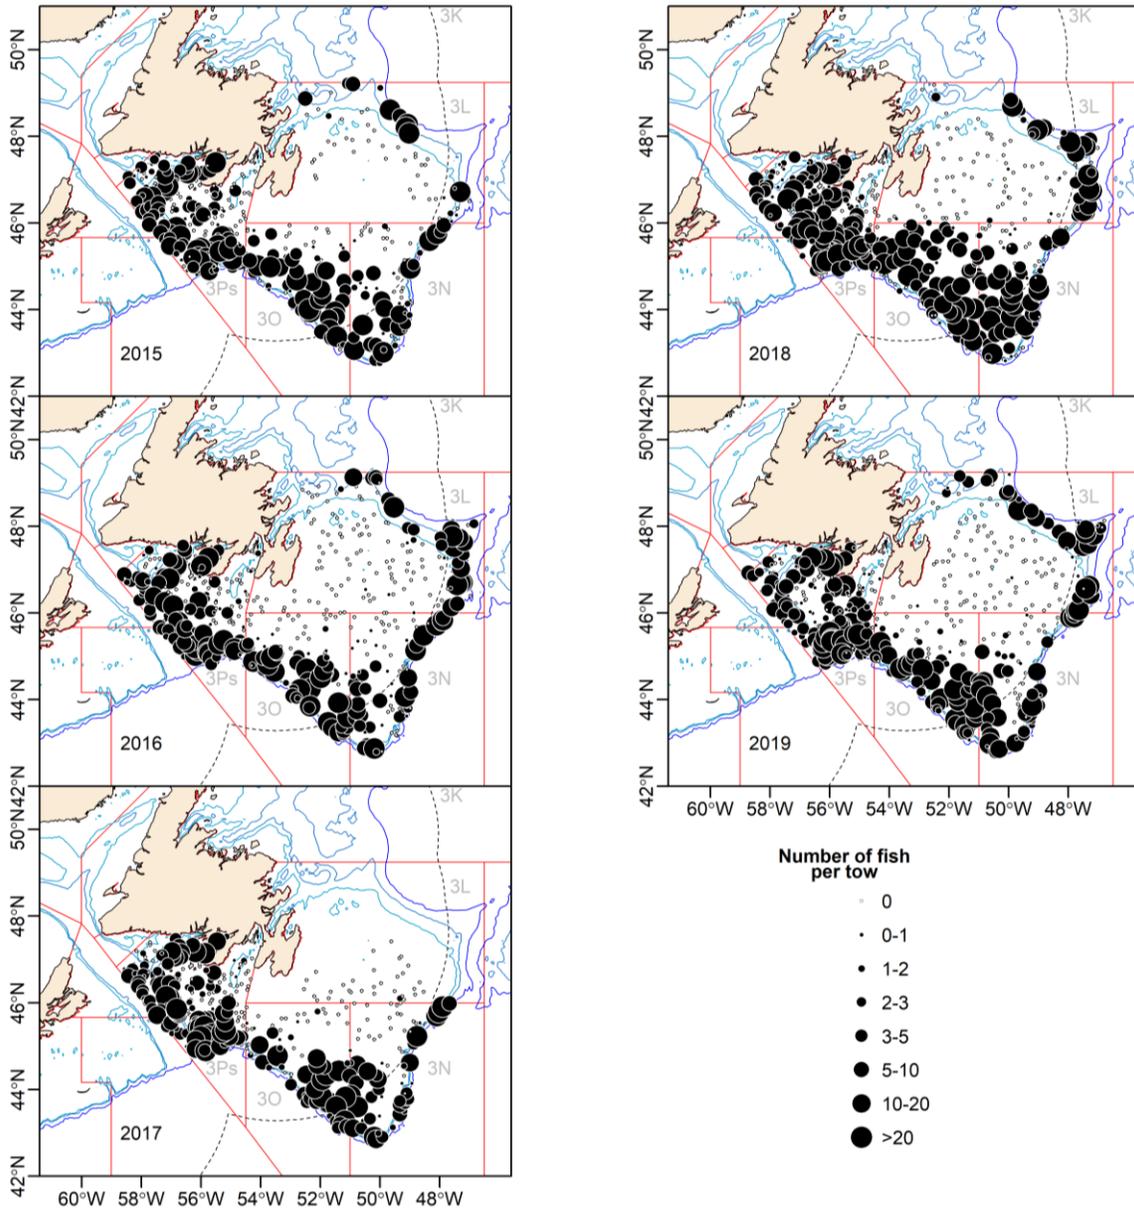

Figure 14b. Distribution (number of skates per tow) of Thorny Skate on the Grand Banks (Divs. 3LNOPs) during Canadian spring surveys, 2015-2019. The Div. 3L survey was incomplete in 2015 and 2017.

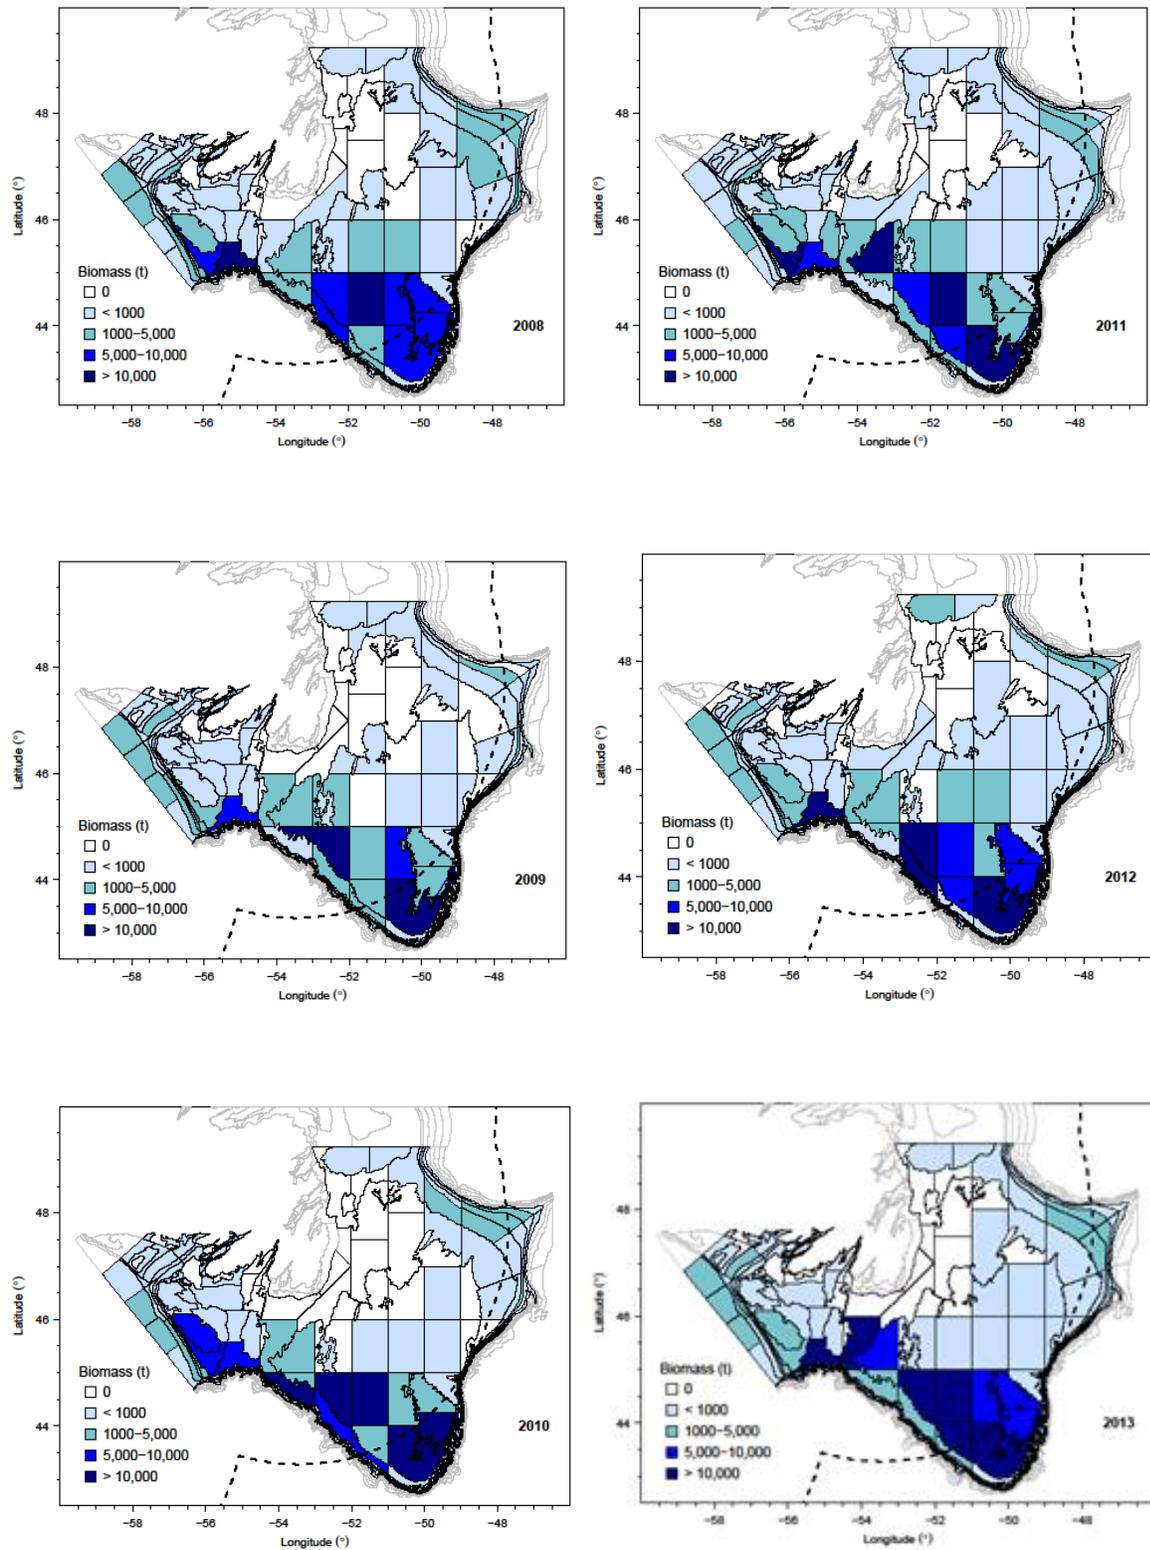

Figure 15a. Distribution (biomass in tons) of Thorny Skate on the Grand Banks (Divs. 3LNOPs) during Canadian spring surveys, 2008-2013.

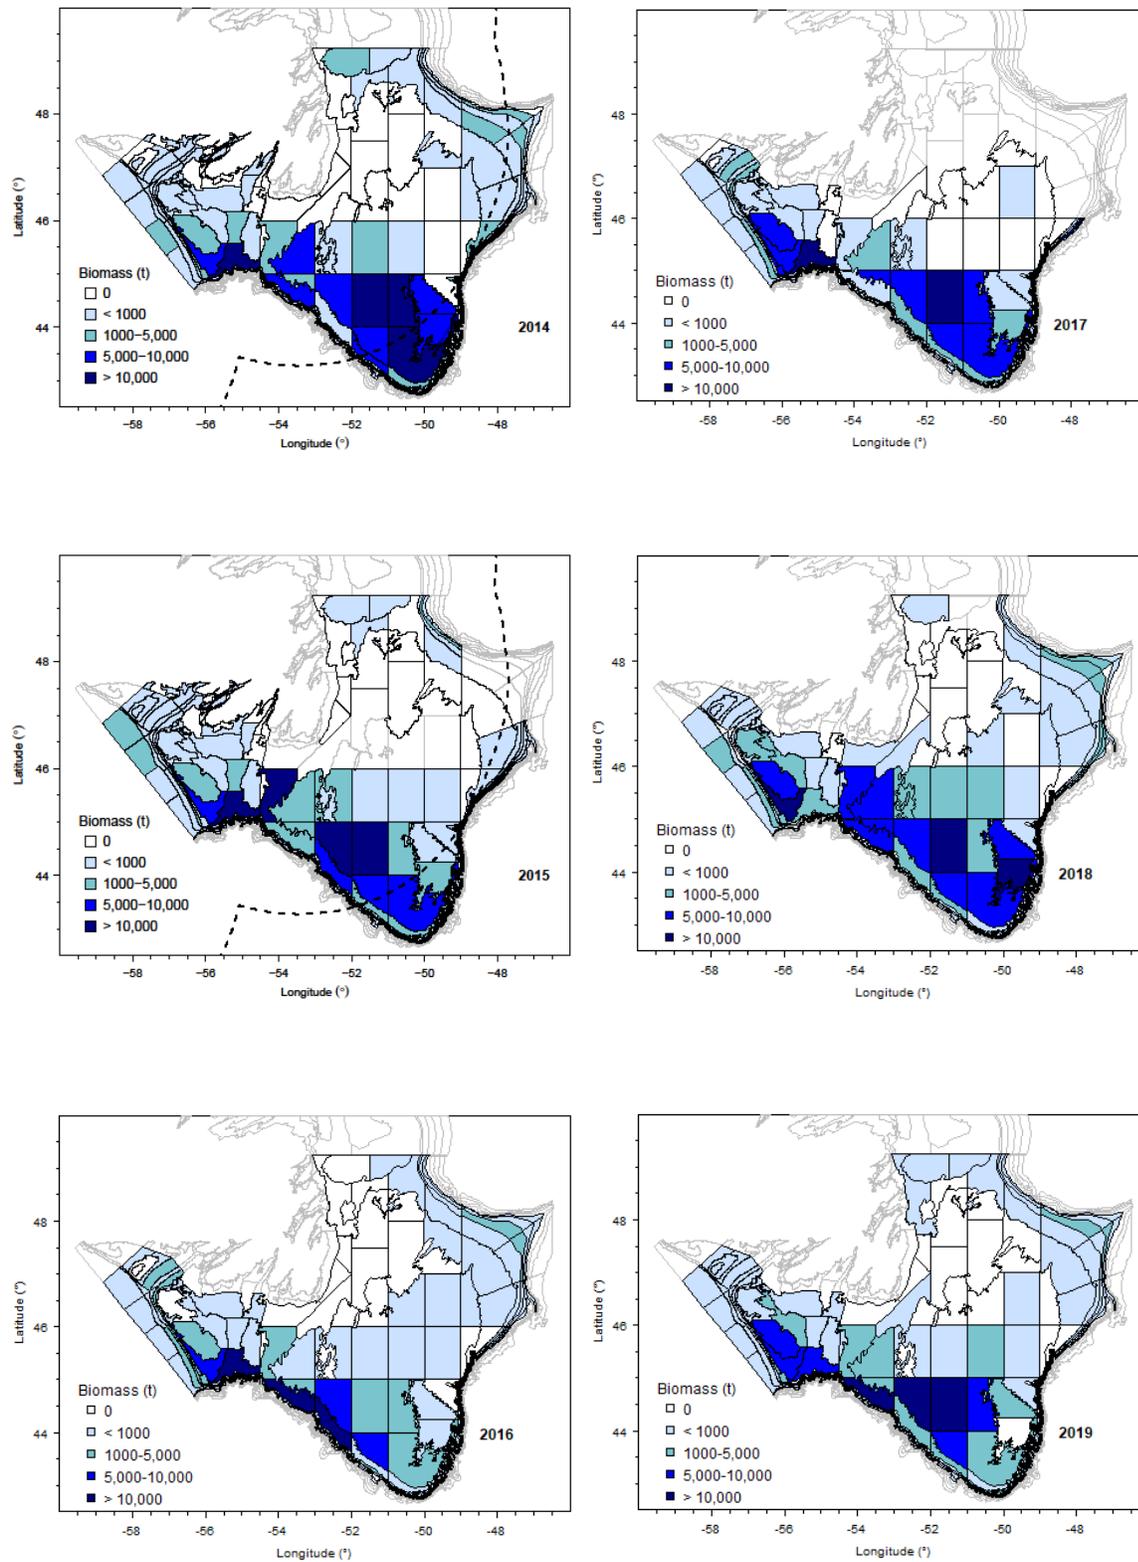

Figure 15b. Distribution (biomass in tons) of Thorny Skate on the Grand Banks (Divs. 3LNOPs) during Canadian spring surveys, 2014-2019. The Div. 3L survey was incomplete in 2015 and 2017.

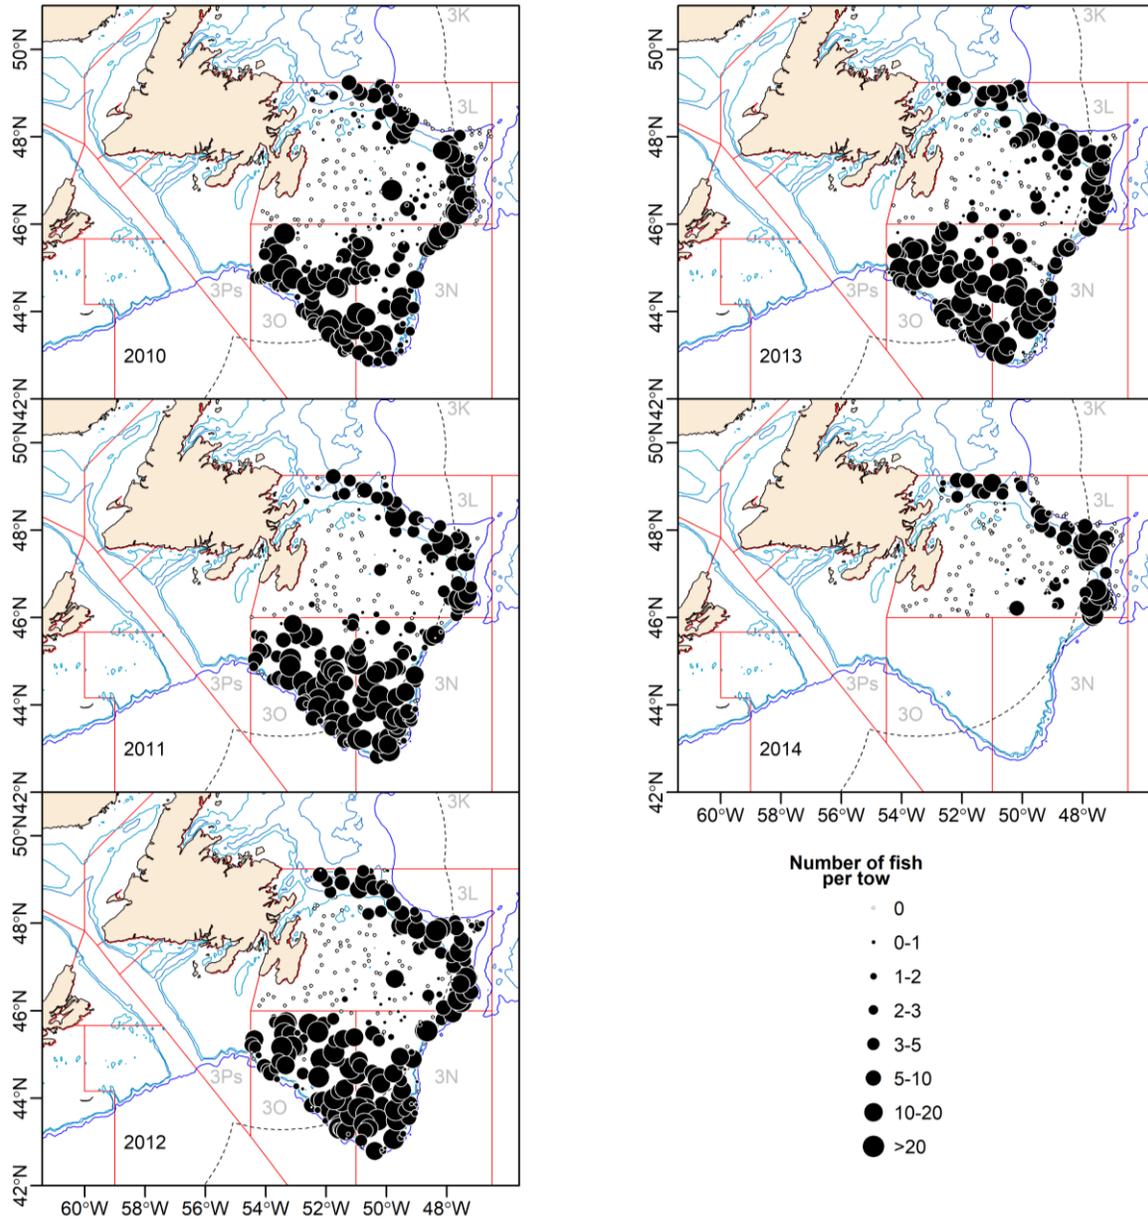

Figure 16a. Distribution (number of skates per tow) of Thorny Skate on the Grand Banks (Divs. 3LNO) during Canadian fall surveys, 2010-2014. Divs. 3NO were not surveyed in 2014.

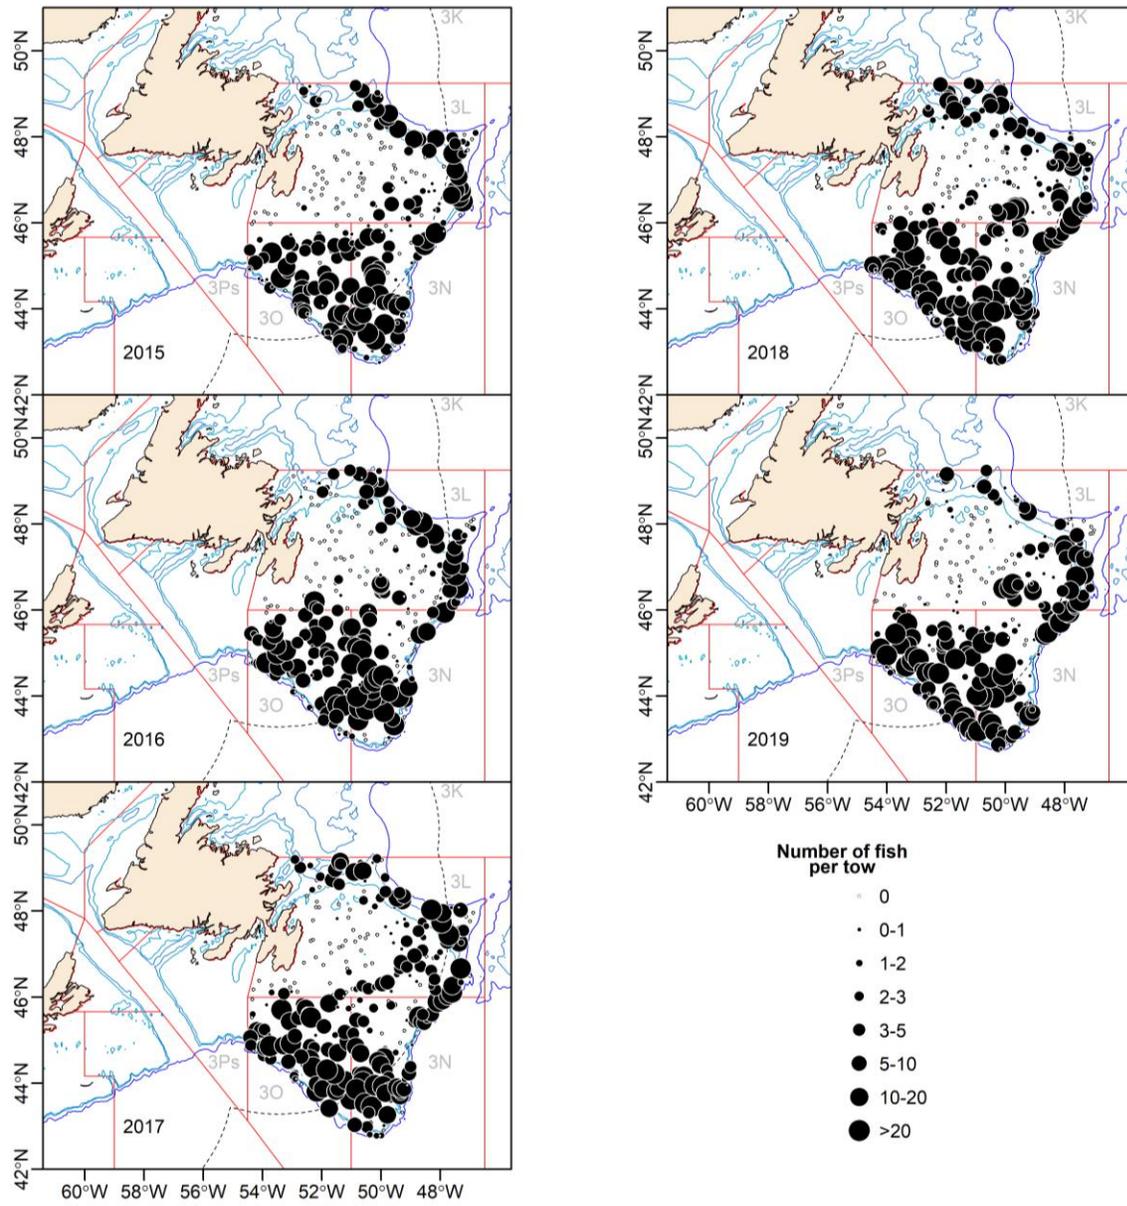

Figure 16b. Distribution (number of skates per tow) of Thorny Skate on the Grand Banks (Divs. 3LNO) during Canadian fall surveys, 2015-2019.
