## SCIENTIFIC COUNCIL MEETING - IUNE 2022

An assessment of the Witch flounder resource in NAFO Divisions 3NO

by

D. Maddock Parsons, R. Rideout and B. Rogers

Fisheries and Oceans Canada

P.O. Box 5667 St. John's, Canada, A1C 5X1

#### Abstract

In 2021 Canadian catch was estimated at 386 t and non-Canadian catch estimated at 239 t for a total catch of 625 t of an available 1175 t quota. Spring survey indices in NAFO Divs. 3NO increased from 2010 to 2013 before a sharp decline in both biomass and abundance from 2013 to 2015. Since then, levels have increased slightly or remained stable. The fall survey indices for NAFO Divs. 3NO declined sharply from 2009 to 2016 to values approaching the lowest of the time series. The fall biomass index increased from 2016-2019, but declined in 2020. Driven by abundance indices in NAFO Div. 30, the fall survey abundance index for NAFO Div. 3NO combined increased sharply in 2019 before declining in 2020. COVID-19 and problems with the research vessels prevented surveys of NAFO Divs. 3NO in spring 2020 and 2021, as well as the fall survey in 2021.

A surplus production model in a Bayesian framework is used to provide TAC advice for this stock. Relative estimates from the model indicate that stock size decreased from the late 1960 s to the late 1990 s and then increased from 1999 to 2013. There was a large decline from 2013 to 2015, with a subsequent small increase since. The model suggests that a maximum sustainable yield (MSY) of 3824 t ( $3050 \mathrm{t}-4650 \mathrm{t}$ ) can be produced by total stock biomass ( $B_{m s y}$ ) of $60510 \mathrm{t}\left(46500 \mathrm{t}-73800 \mathrm{t}\right.$ ) at a fishing mortality rate ( $F_{m s y}$ ) of 0.062 (0.050.09 ). In 2021, the stock is at $47 \% B_{m s y}$ with a 0.095 risk of being below $B_{l i m}$. Median $F$ was estimated to be $36 \%$ of $F_{m s y}$ with a low probability ( 0.01 ) of being above $F_{m s y}$ in 2021. The population was projected to 2025 under varying levels of fishing and catch. The probability of projected biomass being below Blim by 2025 was 5 to $9 \%$ in all catch scenarios examined and for the $F=0$ projections, $\mathrm{P}\left(B<B_{l i m}\right)$ was $3 \%$ or $4 \%$ by 2025 , for catch in 2022 assumed at TAC (1175t) or recent levels ( 700 t ; 2017-2021 average), respectively.

Key words: 3NO witch, surplus production model, assessment

## Fisheries and Management

As noted in previous reports (Lee et al. 2014 and Brodie et al. 2011), species-specific catch statistics for flatfish prior to 1973 were largely developed from breakdowns of unspecified flounders and therefore should be considered with caution. Catches in the 1960 s peaked at $11000-12000$ tonnes ( t ) in 1967-68 and remained relatively high during the next several years (Table 1; Fig. 1). Catch reached a time series high of 15000 t in 1971 and subsequently declined over the next decade to levels between 2000 and 4000 t in the early 1980s (Table1; Fig. 1).

The first total allowable catch (TAC) for witch flounder was introduced by ICNAF in 1974 at a level of 10000 t ,
largely based on average historical catches (Table 1; Fig. 1). This remained in effect until 1979 when it was reduced to 7000 t in consideration of declining commercial catch rates. It was further reduced to 5000 t in 1981 and remained at that level until 1993. The Scientific Council (SC) advised that for 1994, catches from this stock should not exceed 3000 t . A TAC of 3000 t was agreed by the NAFO Fisheries Commission, however, it was also agreed that no directed fishery would be conducted for witch flounder in 1994 to permit rebuilding due to the poor state of the stock. The NAFO Fisheries Commission (FC) introduced a complete moratorium for directed fishing in 1995, which was continued through 2014. There was no directed fishing on this stock from 1994 to 2014. A 1000 t TAC was adopted for $3 N O$ witch flounder beginning in 2015. Despite the 1000 t quota available, the catch reported for 2015 ( 359 t ) was consistent with the bycatch range (300-400 t) reported since 2010. The TAC increased to 2172 t and 2225 t in 2016 and 2017 respectively, but decreased to 1116 t in 2018. In the 2018, 2019 and 2020 assessments of this stock, based of the probability of the stock being below $B_{\text {lim }}$ in the medium term ( $>10 \%$ ), NAFO SC recommended no directed fishing on witch flounder in 2019-2022. However, FC adopted a TAC of 1175 t in each year for 2019 to 2022.

Annual catches (Table 1; Fig. 1) rose rapidly to around 9000 t in 1985 and 1986 as a result of an increase in fishing effort in the NAFO Regulatory Area, primarily on the "tail" of the Grand Bank in Division 3N. Catches remained relatively high in 1987 and 1988 at around 7500 t . During 1990-93 estimated catches were in the range of 4 200-5 000 t . The estimated catch for 1994 was in the order of 1100 t . A moratorium was introduced for this stock in 1995. The catch dropped to 300 t in 1995 likely as a result of a substantial reduction in fishing effort for Greenland halibut where witch flounder comprises a bycatch. Bycatch then increased steadily and by 1999 was about 800 t , although it declined again to an estimated 450 t in 2002. In 2003, several sources of catch data were available and a single source could not be considered as the most valid. As a result, catches were estimated to be 1544 t in 2003 (midpoint of a range of estimates) which declined to about 200 t in 2007, increased to 421 t in 2010 then declined slightly to about 360 t in 2015. Catches increased in 2016 with the increase in TAC to just over a 1000 t and from 2017 to 2021 catches have ranged from 625 t to 862 t . In 2018 the catch was estimated utilizing the Catch Data Advisory Group (CDAG) methodology. The CDAG method was refined and a new working group formed which developed the Catch Estimation Strategy (CESAG). The CESAG estimates are the accepted catch for this stock, and in 2021 the catch was 625 t .

Historically, the fishery was conducted primarily by Canada and the former Soviet Union (Table 1). Canadian catches fluctuated from between 1200 and 3000 t from 1985-91 but increased to about 4300 t in 1992 and 1993. Canadian catches during the 1995-2014 moratorium averaged 34 t per year. Post moratorium catches by Canada have ranged from 221 t to 799 t, and in 2021386 t of witch were taken. Catches by the Russian vessels declined from between 1000 and 2000 t in the period 1982-88 and averaged 39 t per year during the 1995-2014 moratorium. Catches by Russia were low since directed fishing on this stock resumed, and were primarily bycatch in the Greenland halibut and redfish fisheries. In 2019, Russian vessels resumed directed fishing for witch flounder in NAFO Divs. 3NO and their catch rose to 301 t ( 260 t directed catch; Fomin and Pochtar 2020), however declined again in 2020 and 2021 to 56 t and 82 t respectively. Combined catch from other countries since 1995 has ranged from 80 t (2019) to 1400 t (2003) with an average annual catch of about 360 t.

## Data from commercial fisheries

Length frequencies were available from observer data for Canadian, Spanish and Russian witch flounder fisheries in NAFO Divs. 3NO in 2019. Sampling of the Canadian witch flounder catch in 2019 to 2021 indicated the catch ranged between 29 and 60 cm . Mean length in 2019 was about 43 cm in both NAFO Divisions 3N and 30, but Div. 30 had a wider range of fish with more fish in the $50-60 \mathrm{~cm}$ range. In both 2020 and 2021 mean size of fish in Div. 3N was slightly lower than that in 30 (Fig. 2). Spanish catches for this stock in 2021 were 34 t . Most of the Canadian and Spanish catches were taken in a directed fishery and as by-catch of the Redfish and Greenland halibut fisheries (83\%) and to a lesser degree in the skate fishery (17\%). The bulk of Spanish catches
www.nafo.int
were in the range of 27-49 cm (Fig. 2). Catch of witch flounder by Russian trawlers was 19 t directed and 25 t as by-catch in the redfish fishery, and 41 t in other fisheries.

## Research Vessel Surveys

## Canadian RV surveys

## Spring Surveys

Stratified-random research vessel surveys have been carried out by Canada on the Grand Banks in NAFO Divs. 3NO during spring since 1971, covering depth up to 366 meters until 1991, after which the survey was extended to 731 meters (Tables 2-5). In 1993 only, spring surveys were completed to a depth of 914 m . The 2006 Canadian spring survey in Divs. 3NO was considered to be incomplete due to poor coverage. Spring surveys in Divs. 3NO were completed for most strata in all years from 1991 to 2019 to a depth of 731 m . Due to Covid-19 restrictions, there was no survey completed in spring of 2020, and in 2021 vessel issues prevented completion of the survey in Divisions 3NO. A complete description of the survey, including timing and spatial coverage can be found in Rideout and Ings (2020).

## Fall Surveys

In addition to spring surveys, a time series of fall surveys was begun in 1990 (Tables 6-9). Annual spatial and temporal extent of fall surveys are described in Rideout and Ings (2020). Note that due to operational difficulties there were no fall surveys of NAFO Divs. 3NO in 2014 or 2021. From fall 1998, the survey depth range in Div. 3N was further extended occasionally from the previous maximum depth range of 731 m to 1463 m , with coverage of these deeper strata being sporadic. From fall 2000 the survey depth range in Div. 30 was extended occasionally from the previous maximum depth range of 1097 m to 1463 m , with coverage of these deeper strata being sporadic.

Beginning with the fall survey in 1995, the survey gear was changed from an Engel 145 groundfish trawl with steel bobbin footgear to a Campelen 1800 shrimp trawl with rockhopper footgear. The data from the earlier Engel surveys have been converted to Campelen 1800 trawl catch equivalents. Only the converted survey data are presented but some caution should be used in comparing converted Engel data with data from the Campelen trawl series.

## Biomass and abundance trends in NAFO Divs. 3NO

For spring surveys in NAFO Divs. 3NO the stock indices trends are primarily driven by the higher overall abundance and biomass estimated for NAFO Div. 30. The NAFO Divs. 3NO combined indices for spring show a slow decline in biomass and abundance from 1984 to the late-1990s (Tables 6, 7 \& 10; Figs. 3 \& 5) and although fluctuations continue to occur, some minor improvement in the estimates had occurred from 1998 to 2003 until declining from 2003 to 2005. Values from 2007-2010 have fluctuated around the long-term mean (Fig. 5), however from 2010 to 2013 estimates of both biomass ( 7000 to 24000 t) and abundance ( 20 to 70 million fish) increased substantially, with the time series highest values in 2013 peaking at about 2.5 times the long term mean. This increase from 2010 to 2013 was followed by a sharp decline in both biomass and abundance from 2013 to 2015. Spring survey indices for NAFO Divs. 3NO increased to about the time series mean in 2019. The biomass index remained near the mean in 2019, but the abundance index increased to above the average. Restrictions due to Covid-19 prevented the spring survey in 2020, and problems with the research vessels prevented the 2021 spring survey in NAFO Divisions 3NO.
www.nafo.int

The fall survey series for Divisions 3NO combined (Tables 8 , $9 \& 11$; Figs. $4 \& 5$ ) is less variable with a generally increasing trend in biomass and abundance from about 1997 until 2005. Variability increases substantially from 2006 to 2013. Both biomass and abundance increased substantially from 2007 to 2009 and were 2.75 and 2.5 times the mean, respectively (Fig. 5). This peak (the highest in the time series) is followed by a decreasing trend to 2016 when estimates were below the average. The fall survey biomass index for NAFO Divs. 3NO has increased slightly each year since 2016. The abundance index also showed a slight increase from 2016 to 2018, but increased sharply in 2019 to 1.75 times the average, driven by a three-fold increase in NAFO Div. 30. In 2020, both biomass and abundance indices declined to levels similar to 2018. There was no survey in fall 2021 due to problems with the research vessels.

## Depth distribution

Witch flounder have been described as a relatively deep water species, having been captured at depths of up to 1500 m. However, in the Newfoundland \& Labrador area, they are thought to prefer depths of $184-366 \mathrm{~m}$ (Bowering and Brodie 1991) with previous studies showing that witch flounder in 3NO exhibit different depth preferences depending on season and division (Dwyer 2008; SCWP 15/014). A higher percentage of the biomass in 3 N is found in deeper strata, but there is still a large percentage found in depths of less than 100 m , especially in the fall. In Div. 30 where the main component of the stock is distributed, a large proportion of the biomass is found in depths less than 183 m in either spring or fall. This is despite the fact that in a number of years, the survey covered depths of up to 1500 m in the fall.

As discussed in Dwyer (2008), distribution plots indicated more witch flounder are distributed on the shallower, shelf area of the Grand Banks in some years, especially in Div. 30 and especially in the fall. Therefore, it seems likely that the RV survey coverage does adequately cover the depth distribution of witch flounder, particularly in the fall. The variation in the survey indices may be due to the movement of flounder onto and off of the shelf areas depending on water temperatures and spawning aggregations. Bowering and Orr (1996) suggested that the movement of witch flounder onto the shallow parts of the bank in large strata cause the high variability in annual stock size estimates. It is also likely that some witch flounder may be distributed outside the survey area, particularly in the spring, following spawning in deeper waters, and this may also contribute to variability in survey estimates.

## Distribution Plots

Geographic distributions of witch flounder for recent years are presented in Figures 6-9 as number and weight (kg) per tow in the spring (2013-2021; no survey in 2020 or 2021) and fall surveys ( 2013 to 2021; 2014 survey incomplete and no survey in 2021). The witch flounder stock for Div. 3NO is mainly distributed in Div. 30 along the southwestern slope of the Grand Bank. In most years the distribution is concentrated along this slope but during the fall it has a wider distribution in the shallower parts of the bank. It is this variation in distribution from deeper to shallower strata in conjunction with the survey timing that is often responsible, in part, for the high variability in the annual biomass and abundance indices (Bowering and Orr 1996).

## Length frequencies

Canadian (1996-2020) and Spanish (2003-2021) RV survey length frequency data for individual years from are presented in Figure 10 as abundance at length. Ageing information has not been available from Canadian RV surveys since the mid 1990's, making the tracking of cohorts from length frequency data difficult given
the relatively slow growth of witch flounder. However, some trends in size classes of witch flounder are evident. Length frequencies of $30-50 \mathrm{~cm}$ fish (generally, recruited sizes) increased from 2003 to 2005, decreased to pre-2002 levels from 2006 to 2007, and were then consistently higher from 2008 to 2014 (note there was no survey data collected in the fall of 2014) with a mode generally within the mode of 40 cm . The increase in $30-50 \mathrm{~cm}$ fish is generally more pronounced in the fall survey data as opposed to the flatter distributions of the spring surveys. From 2015 to 2019 , fish at this size mode were less prominent than seen in 2008 to 2014, although in fall 2020 this larger mode of fish increased.

Considering smaller fish and indications of recruitment to the stock, there have been a few identifiable peaks in the time series (Fig. 10) that could be followed in successive years (e.g. peak at 9 cm in 1997, 11 cm in 1998, and 20 cm in 1999; peak at 13 cm in 2011, and 20 cm in 2013). These smaller modes tracking through the survey series could indicate recruitment of year classes. In 2002, however, a peak at 12 cm was not observed subsequently. There have been less distinctive peaks, usually in the $10-20 \mathrm{~cm}$ range (2007, 2011, and 2015) although they were not identified in subsequent years. In the fall survey of 2017 a mode in the $10-15 \mathrm{~cm}$ range was observed, and this mode can be seen to progress through the spring survey at about 15 cm . The mode does not appear strong in the fall survey of that year, but is seen again in the 2019 spring survey (19$21 \mathrm{~cm})$ and is a strong mode in the fall survey of $2019(22-24 \mathrm{~cm})$. In 2019, a strong mode is seen of fish in the 6 to 10 cm range. This mode is again observed in the fall survey advancing to 8 to 14 cm . Unfortunately, there was no spring survey in 2020, and in the fall survey, there was no indication of this significant peak of smaller fish. With no surveys in 2021, it is difficult to say if this apparent recruitment peak has persisted.

Abundance at length in the Spanish spring RV surveys was fairly consistent at $33-35 \mathrm{~cm}$ from 2003 to 2007 (a smaller range than the Canadian surveys during the same time period). From 2008 to 2017 the size range has generally increased with more fish in the $38-40 \mathrm{~cm}$ range. In 2018 the mode was in the $38-40 \mathrm{~cm}$ range (Fig. 10) and few fish are observed in the 2019 survey, with a very flat distribution. In 2021, this survey again shows fish in the $29-57 \mathrm{~cm}$ size range, but there is no indication of recruitment peaks of smaller fish in the areas covered by this survey.

## Recruitment

Figure 11 shows the abundance index for fish less than 21 cm (a recruitment proxy) for NAFO Divs. 3NO combined, as measured in the spring and fall Canadian RV surveys. Up until 2018, recruitment indices from spring surveys were above the series mean in 1997 (3X), 2009 and 2013 and 2018. Fall indices were above the mean in 1998, 1999, 2000 and 2002. In 2019, both spring and fall surveys showed a recruitment index 5 times higher than the time series mean. The 2020 fall index was below average once again, however, and with lack of other surveys in 2020 and 2021, it is difficult to determine current recruitment. Most other values since 2002 have been consistently below or at the mean of the time series. Recruitment in spring and fall surveys in 2016 approached the lowest values of the time series. Previous work (Rogers and Morgan 2019) to answer a research recommendation has examined the apparent lack of fish in the $20-30 \mathrm{~cm}$ range as seen in the length frequency distributions of the stock prior to 2019, and did not find any evidence that pre-recruits might be coming from an adjacent stock area (NAFO Div. 3L or Subdivision 3Ps).

The distributions of juvenile ( $<21 \mathrm{~cm}$ ) witch flounder over the spring and fall Canadian surveys indicate a marginal pattern of fish being more widely distributed over the shallower depths in the larger strata during the fall. It is also possible that the weak pattern may be related to the distributions previously presented for the entire population which indicated a movement of fish to the shallower, larger strata during the fall. (Bowering and Orr 1996). The distribution of small witch flounder in the Canadian surveys of NAFO Divs. 3NO in spring and fall of 2018-2021 are shown in Fig. 12.

## Recent History of the assessment of this stock

For many years, the status of the witch flounder stock in NAFO Divs. 3NO was assessed based on catch and survey results, as no analytical model was available. Complicating attempts to fit analytical models to the stock was the absence of aging data (there has been no aging available for witch flounder since 1994). In 2006, a nonequilibrium surplus production model incorporating covariates (ASPIC; Prager, 1994, 1995) was applied to catch and survey biomass indices in order to investigate the usefulness of this method in quantitative assessment of this stock. This production model was rejected based on indicators of poor model suitability including unreasonably high $B / B_{m s y}$ ratio, poor observed to estimated CPUE relationship, and strong residual patterns (Maddock Parsons 2006). A proxy for $B_{\text {lim }}$ similar to those used in other stocks (15\% highest observed survey biomass) was not considered appropriate in assessments conducted from 2006-2013, due to survey variability (over time, and between season) and depth coverage differences over the survey time series.

In 2014, the application of a surplus production model in a Bayesian framework was explored. A variety of combinations of input data and prior distributions on the parameters was tested. Model results were found to be sensitive to the choice of the prior on survey catchabilities, and therefore, the model was rejected. Proxies for $B_{l i m}$ and $F_{l i m}$ were accepted for the first time in this 2014 assessment. They were based on the two highest Canadian spring survey biomass index values from 1984-2013 as a proxy for $B_{l i m}$ and considering $30 \%$ of this value to be the limit (as in SCS Doc 04/12) and $F_{\text {lim }}=F_{m s y}$ was derived from the catch/biomass ratio (Lee et al. 2014). Further work to explore the input series to the Bayesian surplus production model for this stock considered the input series and sensitivity of the model results to the choice of priors was conducted in 2015 (Morgan et al. 2015). Resulting from this work, a surplus production model in a Bayesian framework was accepted for the basis to assess this stock in 2015.

In the 2017 assessment, preliminary model runs indicated that model performance was slightly worse than the previous assessment, and further sensitivity analyses were undertaken to refine the estimates of r and K (Morgan and Lee 2017). In 2018, initial model results indicated that over 2014-2016 the survey indices were declining faster than can be explained by the process being modelled. To account for this a change to the model formulation was accepted to allow the process error to increase in 2014, 2015 and 2016 compared to the rest of the years (the sigma parameter was increased by 1 in those years). A recommendation by STACFIS in 2018 to further explore the prior distributions for the accepted model formulation resulted in no change to the model formulation used in the 2019 assessment (Morgan and Koen-Alonso 2019). The 2020 and 2022 assessment of the stock uses the 2019 accepted formulation, updated with catch and survey indices for most recent years.

## Surplus production model in a Bayesian Framework

For the 2022 assessment model, the Schaefer (1954) form of a surplus production model was used:

$$
\mathrm{Pt}=[\mathrm{Pt}-1+\mathrm{r} \bullet \mathrm{Pt}-1(1-\mathrm{Pt}-1)-\mathrm{Ct}-1 / \mathrm{K}] \bullet \eta \mathrm{t}
$$

Where:

> Pt- 1 is exploitable biomass (as a proportion of carrying capacity) for year $\mathrm{t}-1$ $\mathrm{Ct}-1$ is catch for year $\mathrm{t}-1$ (Meyer and Millar, $1999 \mathrm{a}, 1999 \mathrm{~b}$ ). K is carrying capacity (level of stock biomass at equilibrium prior to commencement of a fishery) r is the intrinsic rate of population growth $\eta \mathrm{t}$ is a random variable describing stochasticity in the population dynamics (process error).

The model utilizes biomass proportional to an estimate of $K$ in order to aid mixing of the Markov Chain Monte Carlo (MCMC) samples and to help minimize autocorrelation between each state and K (Meyer and Millar 1999a, 1999b).

An observation equation is used to relate the unobserved biomass, Pt , to the research vessel survey indices:

$$
\mathrm{It}=\mathrm{q} \bullet \mathrm{Pt} \bullet \varepsilon \mathrm{t}
$$

Where:
q is the catchability parameter
Pt is an estimate of the biomass proportional to $K$ at time $t$
$\varepsilon t$ is observation error
The priors used in the model were:
$\left.\begin{array}{|lll|}\hline \begin{array}{l}\text { Median initial population size } \\ \text { (relative to carrying capacity) }\end{array} & \text { Pin }^{\sim} \text { dunif(0.5, 1) } & \text { uniform(0.5 to 1) } \\ \hline \text { Intrinsic rate of natural increase } & \mathrm{r}^{\sim} \text { dlnorm(-1.763,3.252) } & \text { lognormal (mean, precision) } \\ \hline \text { Carrying capacity } & \mathrm{K}^{\sim} \text { dlnorm(4.562,11.6) } & \text { lognormal (mean, precision) } \\ \hline \text { Survey catchability } & \begin{array}{l}\mathrm{q}=1 / \mathrm{pq} \\ \mathrm{pq} \sim \text { dgamma(1,1) }\end{array} & \text { gamma(shape, rate) } \\ \hline \begin{array}{l}\text { Process error (sigma=standard } \\ \text { deviation of process error in log- } \\ \text { scale) }\end{array} & \begin{array}{l}\text { For 1960-2013 and 2017-2021 } \\ \text { sigma } \sim \text { dunif(0,10) } \\ \text { precision:isigma2 }\end{array} & \text { uniform(0 to 10) } \\ & \begin{array}{l}\text { For 2014-2016 } \\ \text { sigmadev }<- \text {-sigma+1 }\end{array} \\ \text { precision: isigmadev2=sigmadev }\end{array}\right]$

Input data are given in Table 12 and shown in Figure 13 scaled to each series mean. The model formulation is given in Appendix 1. The prior on r was informed by that derived by Swain (2012) for witch flounder in the southern Gulf of St. Lawrence. The prior used here allowed for a higher $r$ than derived by Swain (2012) as some of the morphometric methods explored indicated a higher r. Therefore the mean (0.17) derived by Swain (2012) was used as the central tendency (i.e. the median) but with a larger standard deviation. A mean of 0.2 and standard deviation of 0.12 gives a median of 0.17 on the log normal scale. The prior used therefore was: $\mathrm{R} \sim(-1.763,3.252)$

The prior for K was based on Ecosystem Production Potential modelling (NAFO 2014). This modelling indicated that a reasonable distribution for K would have a mean of 100 and a standard deviation of 30 . K~dlnorm(4.562,11.6).

The input data were catch from 1960-2021, Canadian spring survey series from 1984-1990 (survey max depth 366 m ), Canadian spring survey series from 1991-2019 (survey coverage expanded to depths up to 914m; 2006 survey incomplete; no spring surveys in 2020 or 2021) and the Canadian fall survey series from 1990-2020 (2014 survey incomplete; no fall survey in 2021).

The results of the 2017 assessment (Lee et al. 2017) indicated that over 2014-2016 the survey indices were declining faster than can be explained by the process being modelled. To account for this a change was made to allow the process error to increase in 2014, 2015 and 2016 compared to the rest of the years (the sigma parameter was increased by 1 in those years) (Morgan and Koen-Alonso 2019).

## Resource Status

The surplus production model results are summarized in Table 13 and model fit and diagnostic indicators are shown in Table 16 and in Figures 14-17 as well as Appendix 2. All posteriors were updated from their priors (Figs. 16 \& 17). Model fit to the survey data was relatively good for all surveys and very similar to the 2020 assessment (Figure 14). All convergence diagnostics (Table 16; Appendix 2) indicated that there were no issues with model convergence.

The model indicates that stock size decreased from the late 1960s to the late 1990s and then increased from 1995 to 2013. There was a large decline from 2013 to 2015, with a subsequent small increase since. The model suggests that a maximum sustainable yield (MSY) of 3762 ( $80 \%$ Confidence Interval: $3052-4652$ ) t can be produced by total stock biomass ( $B_{m s y}$ ) of $60510 \mathrm{t}\left(46529 \mathrm{t}-73782 \mathrm{t}\right.$ ) at a fishing mortality rate ( $F_{m s y}$ ) of 0.062 (0.05-0.09).

The analysis showed that relative population size (median $B / B_{m s y}$ ) was below $B_{\text {lim }}=30 \% B_{m s y}$ from 1993-1997. The stock size increased since 1994 to 2013 and then declined from 2013-2015 and has since increased slightly. In 2022 the stock is at $47 \% B_{m s y}$ with a 0.095 risk of being below $B_{\text {lim }}$ (Table 13; Fig. 18). Relative fishing mortality rate (median $F / F^{m s y}$ ) was mostly above 1.0 from the late 1960 s to the mid-1990s. $F$ has been below $F_{m s y}$ since the moratorium implemented in 1995 (Table 13; Fig. 19). Median $F$ was estimated to be $36 \%$ of $F_{m s y}$ with a very low probability (0.01) of being above $F_{m s y}$ in 2022.

## Precautionary Approach Framework

The surplus production model outputs indicate that the stock is presently $47 \%$ of $B_{m s y}$ and $F$ is below $F_{m s y}$ (53\%; Fig. 20). $30 \% B_{m s y}$ is considered a suitable limit reference point ( $B_{l i m}$ ) for stocks where a production model is used. At present, the risk of the stock being below $B_{l i m}=30 \% B_{m s y}$ is $9.5 \%$ and risk of $F>F_{m s y}$ is low (1\%). Although no buffers (for $F$ or $B$ ) are defined, this stock is in the cautious zone or the danger zone as defined in the NAFO Precautionary Approach Framework (NAFO 2004).

The posterior distributions (13 500 samples) for $\mathrm{r}, \mathrm{K}$, sigma, and biomass and the production model equation were used to project the population to 2025 . Two catch scenarios were projected: catch in 2022 was assumed equal to the TAC of $1175 t$ and catch in 2022 set to the recent five year average ( 700 t ). For both scenarios, constant fishing mortality for 2023 and 2024 at several levels of $F\left(F=0, F_{2021}, 2 / 3 F_{m s y}, 85 \% F_{m s y}\right.$, and $F_{m s y}$ ) were applied and results are given in tables 14 and 15. A projection with constant levels of catch at 1175 t (TAC in 2022) was also conducted. Figure 21 shows the plot of the projections for the assumption of catch $2022=1175 \mathrm{t}$.

The probability that $F>F_{\text {lim }}$ in 2022 is $14 \%$ at a catch of 1175 t . The probability of $F>F_{\text {lim }}$ ranged from 1 to $50 \%$ for the catch scenarios tested (Table 14). The population is projected to grow under all scenarios, although except for projections of no or very low catch, the probability that the biomass in 2025 is greater than the biomass in 2022 is about $60 \%-70 \%$, which translates into little to moderate growth to 2025 . The population is projected to remain below $B_{m s y}$ through to the beginning of 2025 for all levels of $F$ examined with a probability of greater than $85 \%$. The probability of projected biomass being below $B_{\text {lim }}$ by 2025 was 5 to $9 \%$ in all catch scenarios examined and for the $F=0$ projections, $\mathrm{P}(B<B \lim )$ was $3 \%$ or $4 \%$ by 2025 , for catch in 2022 assumed at TAC ( 1175 t ) or recent levels ( 700 t ; 2017-2021 average), respectively. Figure 21 shows the projected relative biomass over 2022-2025 for both catch scenarios: catch in 2022=TAC ( 1175 t ) and catch in $2022=700 \mathrm{t}$.

Note: Although a TAC of 3000 t was agreed by the Fisheries Commission (FC), it was also agreed that no directed fishing on witch flounder in NAFO Divs. 3NO take place during 1994 due to the poor state of the stock. Canadian catch prior to 2017 was derived from combining Newfoundland and Maritimes commercial data. Canadian, Russian, and "Other". Catch in 2017 was derived from the Catch Data Advisory Group (CDAG) method and in 2018-2021 was estimated by the Catch Estimate Strategy Group (CESAG). A 1,175 ton quota for 3NO witch flounder has been adopted by the Fisheries Commission since 2019.

Table 2. Estimated Abundance ( 000 s ) of witch flounder ( $\mathrm{M}+\mathrm{F}$ ) by stratum from surveys in Divs. 3NO during spring of 1984-2000 (Engel 145 data converted to Campelen Units 1984-1995). Totals and $95 \%$ confidence limits given in millions.

Table 5. Estimated biomass ( t ) of witch flounder ( $\mathrm{M}+\mathrm{F}$ ) by stratum from surveys in Divs. 3NO during spring of 2001-2021. (Engel 145 data converted to Campelen Units from 1990-1995). Totals and $95 \%$ confidence limits given in (' 000 t ). Survey coverage in 2006 was incomplete, and there were no spring surveys in Divs. 3NO in 2020 or 2021.

Table 10. Summary of abundance (' 000 s ), mean number, biomass (' 000 t ) and mean weight (kg) per tow for witch flounder in Canadian Spring surveys (1984-2021) of NAFO Divs. 3NO. Data prior to 1996 are Campelen equivalents. Survey converage was incomplete in 2006 and there were no spring surveys in Divs. 3NO in 2020 or 2021.

Table 16. Convergence criteria and diagnostics for 2022 witch flounder Bayesian surplus production model.

Figure 1. Commercial catch of witch flounder in NAFO Divs. 3NO from 1960-2022 and total allowable catch (TACs).

Figure 2. Witch flounder length frequency (cm) distributions for commercial fisheries by Spain and Canada in NAFO Divs. 3NO.

Figure 3. Biomass (' 000 st), abundance (millions), with associated $95 \%$ confidence intervals, for witch flounder from Canadian spring RV surveys in NAFO Divs. 3 N and 30 during 1984-2021. The 2006 Canadian spring survey in NAFO Divs. 3NO was incomplete and coverage is not considered representative. There were no spring surveys in Divs. 3NO in 2020 or 2021.

Figure 4. Biomass (' 000 st ), abundance (millions), with associated $95 \%$ confidence intervals, for witch flounder from Canadian fall RV surveys in NAFO Divs. 3 N and 30 during 1984-2021. The 2014 Canadian fall survey in NAFO Divs. 3NO was incomplete and coverage is not considered representative. There was no fall survey in Divs. 3NO in 2021.

## Canadian Fall

Figure 5. Biomass and abundance indices scaled to the series means for witch flounder from Canadian fall RV surveys in NAFO Divs. 3N and 30 during 1984-2021. The 2006 spring and 2014 fall surveys in NAFO Divs. 3NO were incomplete and coverage is not considered representative. There were no surveys in Divs. 3NO in spring of 2020 or 2021 nor in fall of 2021.

## Number

$$
+0 \cdot 10 \cdot 100 \bullet 250
$$

Figure 6. Distribution of witch flounder (total number per tow) from Canadian spring RV surveys in NAFO Divs. 3NO from 2013 to 2021. Spring surveys were not conducted in 2020 or 2021.

Weight (kg)
+0 - 10 - 100 250
Figure 7. Distribution of witch flounder (total weight (kg) per tow) from Canadian spring RV surveys in NAFO Divs. 3NO from 2013 to 2021. Spring surveys were not conducted in 2020 or 2021.

Number
$+0 \cdot 10 \cdot 100 \bullet 250$
Figure 8. Distribution of witch flounder (total number per tow) from Canadian fall RV surveys in NAFO Divs. 3NO from 2013 to 2021. There were no fall surveys in 2014 or 2021.

Weight (kg)

$$
+0 \cdot 10 \bullet 100 \bigcirc 250
$$

Figure 9. Distribution of witch flounder (total weight (kg) per tow) from Canadian fall RV surveys in NAFO Divs. 3NO from 2013 to 2021. There were no fall surveys in 2014 or 2021.

Figure 10. Length frequency distributions of witch flounder from Canadian spring and fall and Spanish spring surveys using the Campelen 1800 shrimp trawl. Estimates represent abundance at length (cm) of the surveyed area. All distributions are for NAFO Divs. 3NO combined.

Figure 11. Recruitment index (annual number of witch flounder $<21 \mathrm{~cm}$ scaled to the series mean) spring and fall Canadian RV surveys in NAFO Divs. 3NO 1996-2021. Surveys in spring 2006 and fall 2014 were incomplete and are not considered representative. There were no surveys in Divs. 3NO in spring of 2020 and 2021, nor in fall of 2021.

Figure 12. Distribution of pre-recruit ( $<21 \mathrm{~cm}$ ) witch flounder abundance for Canadian spring (top panels) and fall (bottom panels) surveys of NAFO Divs. 3 NO . Sets without witch flounder $<21 \mathrm{~cm}$ are denoted by " + ".

Figure 13. Catch and indices (scaled to the series mean) input into the surplus production model in a Bayesian framework for the 2022 assessment of witch flounder in NAFO Divs. 3NO.

## 3NO witch

Figure 14. Process error (with $10^{\text {th }}$ and $90^{\text {th }}$ credible intervals) from the surplus production model fit to 3NO witch flounder with process error allowed to increase in 2014-2016.

Figure 15. Observed and predicted survey indices from each of the three surveys used in the model. For each survey the top panel gives the observed and predicted values with $10^{\text {th }}$ and $90^{\text {th }}$ credible intervals while the bottom panel presents standardized residuals.

Figure 16. Priors (red dotted line) and posteriors (black line) for $K, r$ and sigma (process error).

Figure 17. Priors (red histogram) and posteriors (black lines) for $p q$ (inverse of $q$ ) and observation error for the 3 survey indices used in the model.

Figure 18. Witch flounder in Divs. 3NO. Median relative biomass (Biomass $/ B_{M S Y}$ ) with $10^{\text {th }}$ and $90^{\text {th }}$ percentiles 1960-2021. The horizontal lines are $B_{m s y}$ and $B_{l i m}=30 \% B_{m s y}$.

Figure 19. Witch flounder in Divs. 3NO. Median relative fishing mortality ( $F / F_{M S Y}$ ) with $10^{\text {th }}$ and $90^{\text {th }}$ percentiles shown from 1960-2021. The horizontal line is $F_{\text {lim }}=F_{M S Y}$.

Figure 20. Witch flounder in Divs. 3NO: a stock trajectory estimated in the surplus production analysis, under a precautionary approach framework.

Figure 21. Witch flounder in Divs. 3NO: medium term projections of relative biomass $\left(B / B_{m s y}\right)$ at five levels of $\mathrm{F}\left(F=0, F_{2021}, 2 / 3 F_{m s y}, 85 \% F_{m s y}, F_{m s y}\right.$ and constant catch of 1175 t . A catch of 1175 t (TAC) is assumed in 2022. The 10th and 90th credible intervals are shown for the model results up to 2021 (top panel) and for the F0 projection from 2021-2025.

Figure 22. Witch flounder in Divs. 3NO: medium term projections of relative biomass ( $B / B_{m s y}$ ) at five levels of $F\left(F=0, F_{2021}, 2 / 3 F_{m s y}, 85 \% F_{m s y}, F_{m s y}\right.$ and constant catch of 1175 t . A catch of 700 t (average catch 2017-2021) is assumed in 2022. The 10th and 90th credible intervals are shown for the model results up to 2021 (top panel) and for the $F 0$ projection from 2021-2025.

Appendix 1. Model script for 2022 Assessment of 3NO witch flounder in NAFO Divs. 3NO.
