ICNAF Res. Doc. 78/VI/66

ANNUAL MEETING - JUNE 1978

Status of the Cod Stock in Divisions 2J, 3KL

by

R. Wells
Department of Fisheries and Environment
Fisheries and Marine Service
Research and Resource Services
St. John's, Newfoundland

Nominal Catches

Catches in this area declined from an average of about 640,000 tons in 1966-70 to about 380,000 tons in 1971-75. Recent annual catches (1977 being provisional) and TAC's are as follows:

	<u>1973</u>	<u>1974</u>	<u>1975</u>	<u>1976</u>	<u>1977</u>
TAC (000 tons)	666	657	554	300	160
Catch (000 tons)	335	373	288	214	170

Estimation of Age Composition of the Catch

Age compositions for 1977 were derived from each yearly quarter and for each gear, ICNAF Division, and for each country separately as the sampling data permitted. Catches were composed largely of the 1972 and 1973 year-classes, as 4- and 5-year-old cod.

Effort and Fishing Mortality

Table 1 shows the mean catch (kg) per hour trawled in Divisions 3K, 3L and 3KL by Soviet research vessel surveys in the period 1971-77. By applying these research catch rates to the whole of the commercial catches in Divisions 2J3KL, the corresponding effort was calculated and the effort estimates for the years 1971-76 are included in Table 2.

Table 2 also shows effort measures derived from the Soviet and Spanish commercial catch and effort statistics for the period 1963-73. Regressions of fishing mortality (derived from VPA) and effort were calculated for each series of effort. The parameters of these regressions, including R values, are shown in Table 2. The R values are low in each case.

The fishing mortalities estimated for 1977 from 1977 effort measures ranged from .28 to .55, and since no regression was substantially superior to another, an average $F = 0.40$ for 1977 was used in the VPA.

Recruitment Estimates

Soviet young fish surveys in Divisions 3K, 3L and 3KL for year-classes 1959-1972 as 3-year-olds were related to estimates of abundance of the same year-classes as 4-year-olds (from VPA). The data used are shown in Table 3. Estimates of the abundance of the 1973 and 1974 year-classes were 530 million and 465 million respectively. Similar data relating the abundance of 2-year-olds from the Soviet surveys to 4-year-olds from VPA lead to an estimate of 432 million for the 1975 year-class (see Table 4).

Research surveys by the Federal Republic of Germany have clearly shown that the 1972 and 1973 year-classes were very strong in comparison with the older age groups in the catches. The 1977 survey results indicate that the 1974 and 1975 year-classes may also be stronger.

A nominal value of abundance of 500 million was used for year-classes subsequent to that of 1975.

Partial Recruitment Patterns

The partial recruitment pattern used is given in Table 5 and represents the smoothed values of fishing mortality for 1976 derived from the VPA.

Weight-At-Age

The weight-at-age estimates derived from the 1977 biological sampling is given in Table 6. These values are substantially higher than those used in the 1977 assessment, and may reflect changes in the area and time of capture of the catches in 1977.

Estimation of Stock Abundance in 1977

Table 7 shows the estimate of abundance at age for the stock in 1977.

Projection of Catches

Table 8 shows the projected catches and spawning biomass, 1978-86, at fishing mortalities of $F = 0.20$ ($F_{0,1}$), $F = 0.16$ and $F = 0.10$. The catch in 1970 was about 170,000 tons and it is assumed that the 1978 TAC of 135,000 tons will be taken. For each option, catches and spawning biomass increase after 1978.

Table 9 shows the detailed computer output for the projections at $F = 0.20$. The spawning biomass in each year is the total of weights for ages 7-13. In the 1977 assessment, the spawning biomass included ages 7-14.

Table 1. Catch per hour trawled of cod from Soviet research vessel cruises in the period 1971-77.

YEAR	USSR Research Catch per Hour			Total Catch All Countries ('000 tons)
	3K	3L	3KL	
1971	77	138	215	432
